SUPPRESSORS OF CYTOKINE SIGNALING: RELATED REAGENTS

5

10

40

This filing is a PCT Application claiming priority to provisional U.S. Patent Applications USSN 60/055,804, filed August 15, 1997, and USSN 60/053,153, filed July 18, 1997. Also incorporated by reference are provisional U.S. Patent Applications USSN 60/055,853, filed August 15, 1997, and USSN 60/053,244, filed July 18, 1997.

FIELD OF THE INVENTION

The present invention pertains to compositions

related to proteins which function, e.g., in suppressing intracellular signaling pathways, e.g., cytokine signaling. In particular, it provides purified genes, proteins, antibodies, and related reagents useful, e.g., to regulate growth hormone-like or cytokine-regulated intracellular processes, including transcription or genes in various cell types, including immune cells.

BACKGROUND OF THE INVENTION

Recombinant DNA technology refers generally to the technique of integrating genetic information from a donor 25 source into vectors for subsequent processing, such as through introduction into a host, whereby the transferred genetic information is copied and/or expressed in the new environment. Commonly, the genetic information exists in the form of complementary DNA (cDNA) derived from 30 messenger RNA (mRNA) coding for a desired protein product. The carrier is frequently a plasmid having the capacity to incorporate cDNA for later replication in a host and, in some cases, actually to control expression of the cDNA and thereby direct synthesis of the encoded 35 product in the host.

For some time, it has been known that the mammalian immune response is based on a series of complex cellular interactions, called the "immune network". Recent research has provided new insights into the inner

30

35

workings of this network. While it remains clear that much of the response does, in fact, revolve around the network-like interactions of lymphocytes, macrophages, granulocytes, and other cells, immunologists now generally hold the opinion that soluble proteins, known as lymphokines, cytokines, or monokines, play a critical role in controlling these cellular interactions. there is considerable interest in the isolation. characterization, and mechanisms of action of cell 10 modulatory factors, an understanding of which will lead to significant advancements in the diagnosis and therapy of numerous medical abnormalities, e.g., immune system disorders. Some of these factors are hematopoietic growth factors, e.g., granulocyte colony stimulating factor (G-CSF), and others are regulatory molecules. 15 See, e.g., Thomson (1994; ed.) The Cytokine Handbook (2d ed.) Academic Press, San Diego; Metcalf and Nicola (1995) The Hematopoietic Colony Stimulating Factors Cambridge University Press; and Aggarwal and Gutterman (1991) Human 20 Cytokines Blackwell Pub.

Lymphokines apparently mediate cellular activities in a variety of ways. They have been shown to support the proliferation, growth, and differentiation of, e.g., pluripotential hematopoietic stem cells into vast numbers of progenitors comprising diverse cellular lineages making up a complex immune system. Proper and balanced interactions between cellular components are necessary for a healthy developmental or immune response. The different cellular lineages often respond in a different manner when lymphokines are administered in conjunction with other agents.

In the immune system, many of the effects of known cytokines on gene transcription are known to be mediated by cytokine inducible DNA binding proteins. See, e.g., Paul (ed. 1994) <u>Fundamental Immunology</u>, 3rd ed., Raven Press, New York, NY. The mechanisms of signal transduction have been an area of active recent study, and involve protein phosphorylation and dephosphorylation with, e.g., the Janus kinases (JAKs) and Signal

Transducers and Activators of Transcription (Stats). See, e.g., Ihle (1996) <u>Cell</u> 84:331-334; ;Ivashkiv (1995) Immunity 3:1-4; and Ihle and Kerr (1995) Trends in Genetics 11:69-74.

5

10

25

The lack of knowledge regarding the mechanisms of signaling involved in the regulation of cell cycle or transcriptional elements has hampered the ability of medical science to specifically regulate cell division or cellular responses, including immune responses. present invention provides compositions which will be important in such regulation.

SUMMARY OF THE INVENTION

The present invention is based in part upon the discovery of intracellular regulatory molecules which can 15 block signal transduction, e.g., through growth factoror cytokine-receptor superfamily signaling mechanisms. These proteins exhibit a structural feature designated a SOCS box. See Hilton, et al. (1998) Proc. Nat'l Acad. Sci. USA 95:114-119. Moreover, the SOCS3 protein can 20 block the IL-2 induced signaling via the STAT5, establishing function of the SOCS proteins as suppressors of cytokine signaling.

The invention provides a substantially pure or recombinant SOCS14 protein or peptide exhibiting identity over a length of at least about 12 amino acids to SEQ ID NO: 2 or 6; a natural sequence SOCS14 of SEQ ID NO: 2 or 6; a fusion protein comprising SOCS14 sequence; a substantially pure or recombinant SOCS15 (also designated WDS11) protein or peptide exhibiting identity over a 30 length of at least about 12 amino acids to SEQ ID NO: 4 or 8; a natural sequence SOCS15 (WDS11) of SEQ ID NO: 4 or 8; a fusion protein comprising SOCS15 (WDS11) sequence; a substantially pure or recombinant SOCS17 protein or peptide exhibiting identity over a length of 35 at least about 12 amino acids to SEQ ID NO: 10; a natural sequence SOCS17 of SEQ ID NO: 10; a fusion protein comprising SOCS17 sequence; a substantially pure or recombinant SOCS18 protein or peptide exhibiting identity over a length of at least about 12 amino acids to SEQ ID 40

NO: 12; a natural sequence SOCS18 of SEQ ID NO: 12; a fusion protein comprising SOCS18 sequence; a substantially pure or recombinant SOCS19 protein or peptide exhibiting identity over a length of at least about 12 amino acids to SEQ ID NO: 14; a natural sequence SOCS19 of SEQ ID NO: 14; a fusion protein comprising SOCS19 sequence; or a substantially pure or recombinant WDS12 protein or peptide exhibiting identity over a length of at least about 12 amino acids to SEQ ID NO: 16; 10 a natural sequence WDS12 of SEQ ID NO: 16; or a fusion protein comprising WDS12 sequence. In preferred embodiments, the portion is at least about 25 amino In other embodiments, the: SOCS14 comprises a mature sequence of SEQ ID NO: 2 or 6; SOCS15 (WDS11) comprises a mature sequence of SEQ ID NO: 4 or 8; SOCS17 15 comprises a mature sequence of SEQ ID NO: 10; SOCS18 comprises a mature sequence of SEQ ID NO: 12; SOCS19 comprises a mature sequence of SEQ ID NO. 14; WDS12 comprises a mature sequence of SEQ ID NO: 16; protein or 20 peptide: is from a warm blooded animal selected from a mammal, including a primate; comprises at least one polypeptide segment of SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16; exhibits a plurality of portions exhibiting the identity; is a natural allelic variant of SOCS14, SOCS15 25 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; has a length at least about 30 amino acids; exhibits at least two nonoverlapping epitopes which are specific for a mammalian SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; exhibits identity over a length of at least about 20 amino acids to SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, 30 SOCS19, or WDS12; exhibits at least two non-overlapping epitopes which are specific for a SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; exhibits identity over a length of at least about 25 amino acids to a primate SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; 35 is glycosylated; is a synthetic polypeptide; is attached to a solid substrate; is conjugated to another chemical moiety; is a 5-fold or less substitution from natural sequence; or is a deletion or insertion variant from a

natural sequence. Various preferred embodiments include

PCT/US98/14544 WO 99/03993

a composition comprising: a sterile SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein or peptide; the SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein or peptide and a carrier, wherein the carrier is: an aqueous compound, including water, saline, and/or buffer; and/or formulated for oral, rectal, nasal, topical, or parenteral administration. The invention further provides a fusion protein, comprising: mature protein comprising sequence of SEQ ID NO: 2, 6, 4, 8, 10, 12, 14 or 16; a detection or purification tag, including a FLAG, His6, or Ig sequence;

10

15

These reagents also make available a kit comprising such a protein or polypeptide, and: a compartment comprising the protein or polypeptide; and/or instructions for use or disposal of reagents in the kit.

or sequence of another SOCS or WDS protein.

Providing an antigen, the invention further provides a binding compound comprising an antigen binding portion from an antibody, which specifically binds to a natural SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 20 protein, wherein: the protein is a primate protein; the binding compound is an Fv, Fab, or Fab2 fragment; the binding compound is conjugated to another chemical moiety; or the antibody: is raised against a peptide sequence of a mature polypeptide comprising sequence of 25 SEQ ID NO: 2, 6, 4, 8, 10, 12, 14 or 16; is raised against a mature SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; is raised to a purified SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; is immunoselected; is a polyclonal antibody; binds to a 30 denatured SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12; exhibits a Kd to antigen of at least 30 μM; is attached to a solid substrate, including a bead or plastic membrane; is in a sterile composition; or is detectably labeled, including a radioactive or 35 fluorescent label. Preferred kits include those containing the binding compound, and: a compartment comprising the binding compound; and/or instructions for use or disposal of reagents in the kit. Many of the kits

40

will be used for making a qualitative or quantitative analysis.

Other preferred compositions will be those comprising: a sterile binding compound, or the binding compound and a carrier, wherein the carrier is: an aqueous compound, including water, saline, and/or buffer; and/or formulated for oral, rectal, nasal, topical, or parenteral administration.

The present invention further provides an isolated 10 or recombinant nucleic acid encoding a protein or peptide or fusion protein described above, wherein: the SOCS or WDS family protein is from a mammal, including a primate; or the nucleic acid: encodes an antigenic peptide sequence of SEQ ID NO: 2, 6, 4, 8, 10, 12, 14 or 16; 15 encodes a plurality of antigenic peptide sequences of SEO ID NO: 2, 6, 4, 8, 10, 12, 14 or 16; exhibits identity to a natural cDNA encoding the segment; is an expression vector; further comprises an origin of replication; is from a natural source; comprises a detectable label; 20 comprises synthetic nucleotide sequence; is less than 6 kb, preferably less than 3 kb; is from a mammal, including a primate; comprises a natural full length coding sequence; is a hybridization probe for a gene encoding the SOCS or WDS family protein; or is a PCR 25 primer, PCR product, or mutagenesis primer. In certain embodiments, the invention provides a cell or tissue comprising such a recombinant nucleic acid. Preferred cells include: a prokaryotic cell; a eukaryotic cell; a bacterial cell; a yeast cell; an insect cell; a mammalian 30 cell; a mouse cell; a primate cell; or a human cell.

Other kit embodiments include a kit comprising the described nucleic acid, and: a compartment comprising the nucleic acid; a compartment further comprising a SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein or polypeptide; and/or instructions for use or disposal of reagents in the kit. In many versions, the kit is capable of making a qualitative or quantitative analysis.

Other nucleic acid embodiments include those which: hybridize under wash conditions of 50° C and less than 500 mM salt to SEQ ID NO: 1, 3, 5, 7, 9, 11, 13, or 15;

exhibits identity over a stretch of at least about 30 nucleotides to a SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12. In other embodiments: the wash conditions are at 55° C and/or 300 mM salt; 60° C and/or 150 mM salt; the identity is over a stretch is at least 55 or 75 nucleotides.

In other embodiments, the invention provides a method of modulating physiology or development of a cell or tissue culture cells comprising introducing into such cell an agonist or antagonist of a SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

15 I. General

10

20

25

30

35

40

It is to be understood that this invention is not limited to the particular compositions, methods, and techniques described herein, as such compositions, methods, and techniques may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to limit the scope of the present invention which is only limited by the appended claims.

As used herein, including the appended claims, singular forms of words such as "a," "an," and "the" include their corresponding plural referents unless the context clearly dictates otherwise. Thus, e.g., reference to "a polynucleotide" includes one or more different polynucleotides, reference to "a composition" includes one or more of such compositions, and reference to "a method" include reference to equivalent steps and methods known to a person of ordinary skill in the art, and so forth.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by a person of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are

25

30

described below. All publications, patent applications, patents, and other references discussed above are provided solely for their disclosure prior to the filing date of the present application. Nothing herein is to be construed as an admission that the invention is not entitled to antedate any such disclosure by virtue of its prior invention. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety including all figures, references, and drawings.

10 The proliferation, differentiation, and physiological responses of many cell lineages are regulated by secreted proteins, e.g., cytokines. molecules often exert their biological effects through binding to cell surface receptors that are associated with one or more members of the Janus Kinase (Jak) family of cytoplasmic tyrosine kinases. For example, cytokine induced receptor dimerization leads to the activation of JAKs, rapid tyrosine phosphorylation of cytoplasmic 20 domains, and subsequent recruitment of various signaling proteins to the receptor complex, including members of the STAT family of transcription factors. The JAK and STAT proteins are enzymes which act to transduce a signal from the cell surface to the nucleus, thereby serving as the pathway to signal the cell to respond physiologically to an external signal. These pathways have been shown to involve certain protein phosphorylation or dephosphorylation steps, thereby leading to response or lack of response by the cell. See, e.g., Ihle (1996) Cell 84:331-334; Ivashkiv (1995) Immunity 3:1-4; Ihle, et al. (1995) Ann. Rev. Immunol. 13:369-398; Ihle and Kerr (1995) Trends in Genetics 11:69-74; and Darnell, et al. (1994) Science 264:1415-1421.

A number of novel genes have been identified from 35 mouse or humans which appear to inhibit STAT function. See, e.g., Yoshimura, et al. (1995) EMBO J. 14:2816-2826; Matsumoto, et al. (1997) Blood 89:3148-3154; Starr, et al. (1997) Nature 387:917-921; Endo, et al. (1997) Nature 387:921-924; and Naka, et al. Nature 387:924-929.

10

15

40

9 .

present invention provides additional genes with sequence related to those, designated Suppressors Of Cytokine Signaling or WDS: SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12.

A primate, e.g., human, SOCS14 cDNA fragment and corresponding open reading frame are provided in (SEQ ID NO: 1 and 2). The translation exhibits significant matching and similarity to other identified SOCS family members. internal stop codon indicates some errors in the sequence at or near those positions. Additional refined sequence of primate, e.g., human, SOCS14 is provided in SEQ ID NO: 5 and

A rodent, e.g., mouse, SOCS15 cDNA fragment and corresponding open reading frame are provided in SEQ ID NO: 3 and 4. The translation exhibits significant matching and similarity to other identified SOCS family members. The internal stop codon indicates some errors in the sequence at or near those positions.

A rodent, e.g., murine SOCS17 CDNA and corresponding open reading frame are provided in SEQ ID NO: 9 and 10. 20 Nucleotide may be A, C, T, or G at positions: 1680, 1691, 1696, 1704, 1707, 1728, 1740, 1743, 1746, 1755, 1760, 1770, 1773, 1802, 1816, 1817, 1823, 1826, 1827, 1846, 1851, 1857, 1861, 1880, 1885, 1909, 1917, 1920, 1929, 1946, 1953, 1967, 1968, 1980, 1991, 1995, 2001, 2004, 25 2021, 2033, 2034, 2035, 2036, 2037, 2039, 2040, 2042, 2048, 2051, 2054, 2061, 2075, 2081, 2083, 2084, 2085, 2088, 2105, 2121, 2124, 2132, 2137, 2147, 2149, 2151, 2152, 2160, 2165, 2177, 2179 and 2196; nucleotide may be A or C at position 494; nucleotide may be C or T at 30 positions: 498, 501, 1455, 1524, 1527, 1621, 1829, and 2072; nucleotide may be G or C at positions: 499, 1618, and 1664; nucleotide may be G or T at position 1673; and nucleotide may be A, C, or G at positions: 1819, 1840, and 2089 (see SEQ ID NO: 26). 35

A primate, e.g., human, SOCS18 nucleotide and corresponding amino acid sequence are provided in SEQ ID NO: 11 and 12. Nucleotide may be A or C at positions: 740, 797, 2139, and 2184; nucleotide may be G or T at positions: 761, 1313, 1508, and 2226; nucleotide may be C or T at positions 746, 1460, 1499, 2009, 2010, 2199, and 2225; nucleotide may be A or G at positions 788, 863, 1550, 2178, 2188, 2197, and 2211; nucleotide may be G or C at positions: 1163, and 1544; nucleotide may be A or T at positions 2058, and 2128; and nucleotide may be A, C, T, or G at position 2251 (see SEQ ID NO: 27).

A primate, e.g., human, SOCS19 nucleotide and corresponding amino acid sequence are provided in SEQ ID NO: 13 and 14. Nucleotide may be A, C, T, or G at positions: 2078, and 2116; and nucleotide may be G or C at position 2063 (see SEQ ID NO: 28).

Finally, a primate, e.g., human, WDS12 nucleotide and corresponding amino acid sequence is provided in SEQ ID NO: 15 and 16. Nucleotide may be A, C, T, or G at positions: 108, and 109; nucleotide may be A or G at positions: 236, 238, and 1258; nucleotide may be G or T at position 233; nucleotide may be G or C at position 234; nucleotide may be C or T at position 237; and nucleotide may be A or T at position 239 (see SEQ ID NO: 29).

SOCS proteins are a family of proteins ranging from approximately 30-60 Kd which inhibit JAK kinase activity. The amino portion of SOCS proteins contain an SH2 binding motif and the carboxy portion of the molecule contains a SOCS box motif which may play a role in dimerization of SOCS proteins. The WDS are closely related in sequence.

SOCS3 expression is induced by IL-2 and can be detected by approximately 1 hour after IL-2 activation. Subsequently, SOCS expression is decreased relatively rapidly (e.g., approximately 8 hrs after activation). Western blots show that SOCS3 interacts with IL-2 receptor and JAK1 following IL-2 stimulation.

II. Definitions

10

15

20

25

30

The term "binding composition" refers to molecules that bind with specificity to SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein, e.g., in an antibody-antigen interaction. However, other compounds, e.g., binding proteins, may also specifically associate

WO 99/03993 PCT/US98/14544

with SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 proteins in contrast to other molecules. Typically, the association will be in a natural physiologically relevant protein-protein interaction,

either covalent or non-covalent, and may include members of a multiprotein complex, including carrier compounds or dimerization partners. The molecule may be a polymer, or chemical reagent. A functional analog may be a protein with structural modifications, or may be a wholly

unrelated molecule, e.g., which has a molecular shape 10 which interacts with the appropriate protein binding determinants. The proteins may serve as agonists or antagonists of the binding partner, see, e.g., Goodman, et al. (eds.) (1990) Goodman & Gilman's: The

Pharmacological Bases of Therapeutics (8th ed.) Pergamon 15 Press, Tarrytown, N.Y.

The term "binding agent: SOCS or :WDS protein complex", as used herein, refers to a complex of a binding agent and a SOCS14, SOCS15 (WDS11), SOCS17,

SOCS18, SOCS19, or WDS12 protein that is formed by 20 specific binding of the binding agent to the respective SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein. Specific binding of the binding agent means that the binding agent has a specific binding site that

25

30

recognizes a site on the SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein. For example, antibodies raised to a SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein and recognizing an epitope on the SOCS or WDS protein are capable of forming a binding agent: SOCS or :WDS protein complex by specific

binding. Typically, the formation of a binding agent: SOCS or :WDS protein complex allows the measurement of SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein in a mixture of other proteins and biologics.

The term "antibody: SOCS or :WDS protein complex" refers 35 to an embodiment in which the binding agent, e.g., is an The antibody may be monoclonal, polyclonal, or antibody. a binding fragment of an antibody, e.g., an Fv, Fab, or F(ab)2 fragment. The antibody will preferably be a polyclonal antibody for cross-reactivity purposes. 40

15

"Homologous" nucleic acid sequences, when compared, exhibit significant similarity, or identity. The standards for homology in nucleic acids are either measures for homology generally used in the art by sequence comparison and/or phylogenetic relationship, or based upon hybridization conditions. Hybridization conditions are described in greater detail below.

An "isolated" nucleic acid is a nucleic acid, e.g., an RNA, DNA, cDNA, genomic DNA, or a mixed polymer, which is substantially separated from other biologic components which naturally accompany a native sequence, e.g., proteins and flanking genomic sequences from the originating species. The term embraces a nucleic acid sequence which has been removed from its naturally occurring environment, and includes recombinant or cloned DNA isolates and chemically synthesized analogs, or analogs biologically synthesized by heterologous systems. Further, the term includes double-stranded or singlestranded embodiments. Where single-stranded, the nucleic acid may be either the "sense" or the "antisense" strand. A substantially pure molecule includes isolated forms of the molecule. An isolated nucleic acid will usually contain homogeneous nucleic acid molecules, but will, in some embodiments, contain nucleic acids with minor sequence heterogeneity. This heterogeneity is typically found at the polymer ends or portions not critical to a desired biological function or activity.

As used herein, the terms "SOCS" or "WDS" protein shall encompass, when used in a protein context, a protein having amino acid sequences shown in SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16 or a significant fragment of such a protein, preferably a natural embodiment. The term "protein" or "polypeptide" is meant any chain of amino acids, regardless of length or postranslation modification (e.g., glycosylation or phosphorylation). Further, the term encompasses polypeptides which are preor pro-proteins. The invention also embraces a polypeptide which exhibits similar structure to SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein, e.g., which interacts with SOCS or WDS protein specific

10

15

20

25

binding components. These binding components, e.g., antibodies, typically bind to a SOCS or WDS protein, respectively, with high affinity, e.g., at least about 100 nM, usually better than about 30 nM, preferably better than about 10 nM, and more preferably at better than about 3 nM.

The term "polypeptide" or "protein" as used herein includes a significant fragment or segment of a SOCS or WDS protein, and encompasses a stretch of amino acid residues of at least about 8 amino acids, generally at least 10 amino acids, more generally at least 12 amino acids, often at least 14 amino acids, more often at least 16 amino acids, typically at least 18 amino acids, more typically at least 20 amino acids, usually at least 22 amino acids, more usually at least 24 amino acids, preferably at least 26 amino acids, more preferably at least 28 amino acids, and, in particularly preferred embodiments, at least about 30 or more amino acids, e.g., 35, 40, 45, 50, 60, 70, 80, etc. The invention encompasses proteins comprising a plurality of distinct, e.g., nonoverlapping, segments of the specified length. Typically, the plurality will be at least two, more usually at least three, and preferably 5, 7, or even more. While the length minima are provided, longer lengths, of various sizes, may be appropriate, e.g., one of length 7, and two of length 12. Features of one of the different genes should not be taken to limit those of another of the genes.

A "recombinant" nucleic acid is defined either by

its method of production or its structure. In reference
to its method of production, e.g., a product made by a
process, the process is use of recombinant nucleic acid
techniques, e.g., involving human intervention in the
nucleotide sequence, typically selection or production.

Alternatively, it can be a nucleic acid made by
generating a sequence comprising fusion of two fragments
which are not naturally contiguous to each other, but is
meant to exclude products of nature, e.g., naturally
occurring mutants. Thus, for example, products made by

transforming cells with any non-naturally occurring

WO 99/03993 PCT/US98/14544

vector is encompassed, as are nucleic acids comprising sequence derived using any synthetic oligonucleotide process. Such is often done to replace a codon with a redundant codon encoding the same or a conservative amino acid, while typically introducing or removing a sequence recognition site. Alternatively, it is performed to join together nucleic acid segments of desired functions to generate a single genetic entity comprising a desired combination of functions not found in the commonly available natural forms. Restriction enzyme recognition sites are often the target of such artificial manipulations, but other site specific targets, e.g., promoters, DNA replication sites, regulation sequences, control sequences, or other useful features may be incorporated by design. A similar concept is intended for a recombinant, e.g., fusion, polypeptide. Specifically included are synthetic nucleic acids which, by genetic code redundancy, encode polypeptides similar to fragments of these antigens, and fusions of sequences from various different species variants.

10

15

20

"Solubility" is reflected by sedimentation measured in Svedberg units, which are a measure of the sedimentation velocity of a molecule under particular conditions. The determination of the sedimentation velocity was classically performed in an analytical 25 ultracentrifuge, but is typically now performed in a standard ultracentrifuge. See, Freifelder (1982) Physical Biochemistry (2d ed.) W.H. Freeman & Co., San Francisco, CA; and Cantor and Schimmel (1980) Biophysical Chemistry parts 1-3, W.H. Freeman & Co., San Francisco, 30 As a crude determination, a sample containing a putatively soluble polypeptide is spun in a standard full sized ultracentrifuge at about 50K rpm for about 10 minutes, and soluble molecules will remain in the supernatant. A soluble particle or polypeptide will 35 typically be less than about 30S, more typically less than about 15S, usually less than about 10S, more usually less than about 6S, and, in particular embodiments, preferably less than about 4S, and more preferably less than about 3S. Solubility of a polypeptide or fragment 40

depends upon the environment and the polypeptide. Many parameters affect polypeptide solubility, including temperature, electrolyte environment, size and molecular characteristics of the polypeptide, and nature of the solvent. Typically, the temperature at which the polypeptide is used ranges from about 4°C to about 65°C. Usually the temperature at use is greater than about 18°C and more usually greater than about 22°C. For diagnostic purposes, the temperature will usually be about room temperature or warmer, but less than the denaturation temperature of components in the assay. For therapeutic purposes, the temperature will usually be body temperature, typically about 37°C for humans, though under certain situations the temperature may be raised or lowered in situ or in vitro.

10

15

20

25

30

35

40

The size and structure of the polypeptide should generally be in a substantially stable state, and usually not in a denatured state. The polypeptide may be associated with other polypeptides in a quaternary structure, e.g., to confer solubility, or associated with lipids or detergents in a manner which approximates natural lipid bilayer interactions.

The solvent will usually be a biologically compatible buffer, of a type used for preservation of biological activities, and will usually approximate a physiological solvent. Usually the solvent will have a neutral pH, typically between about 5 and 10, and preferably about 7.5. On some occasions, a detergent will be added, typically a mild non-denaturing one, e.g., CHS (cholesteryl hemisuccinate) or CHAPS (3-[3-cholamidopropyl)-dimethylammonio]-1-propane sulfonate), or a low enough concentration as to avoid significant disruption of structural or physiological properties of the protein.

"Substantially pure" in a protein context typically means that the protein is isolated from other contaminating proteins, nucleic acids, and other biologicals derived from the original source organism. Purity, or "isolation" may be assayed by standard methods, and will ordinarily be at least about 50% pure,

more ordinarily at least about 60% pure, generally at least about 70% pure, more generally at least about 80% pure, often at least about 85% pure, more often at least about 90% pure, preferably at least about 95% pure, more preferably at least about 98% pure, and in most preferred embodiments, at least 99% pure. Similar concepts apply, e.g., to antibodies or nucleic acids.

"Substantial similarity" in the nucleic acid sequence comparison context means either that the segments, or their complementary strands, when compared, 10 are identical when optimally aligned, with appropriate nucleotide insertions or deletions, in at least about 50% of the nucleotides, generally at least 56%, more generally at least 59%, ordinarily at least 62%, more 15 ordinarily at least 65%, often at least 68%, more often at least 71%, typically at least 74%, more typically at least 77%, usually at least 80%, more usually at least about 85%, preferably at least about 90%, more preferably at least about 95 to 98% or more, and in particular 20 embodiments, as high at about 99% or more of the nucleotides. Alternatively, substantial similarity exists when the segments will hybridize under selective hybridization conditions, to a strand, or its complement, typically using a sequence derived from SEQ ID NO: 1, 3, 25 5, 7, 9, 11, 13, or 15. Typically, selective hybridization will occur when there is at least about 55% similarity over a stretch of at least about 30 nucleotides, preferably at least about 65% over a stretch of at least about 25 nucleotides, more preferably at least about 75%, and most preferably at least about 90% 30 over about 20 nucleotides. See Kanehisa (1984) Nuc. Acids Res. 12:203-213. The length of similarity comparison, as described, may be over longer stretches, and in certain embodiments will be over a stretch of at least about 17 nucleotides, usually at least about 20 35 nucleotides, more usually at least about 24 nucleotides, typically at least about 28 nucleotides, more typically at least about 40 nucleotides, preferably at least about 50 nucleotides, and more preferably at least about 75 to 100 or more nucleotides, e.g., 150, 200, etc. 40

15

20

25

30

35

40

For sequence comparison, typically one sequence acts as a reference sequence, to which test sequences are compared. When using a sequence comparison algorithm, test and reference sequences are input into a computer, subsequent coordinates are designated, if necessary, and sequence algorithm program parameters are designated. The sequence comparison algorithm then calculates the percent sequence identity for the test sequence(s) relative to the reference sequence, based on the designated program parameters.

PCT/US98/14544

Optical alignment of sequences for comparison can be conducted, e.g., by the local homology algorithm of Smith and Waterman (1981) Adv. Appl. Math. 2:482, by the homology alignment algorithm of Needlman and Wunsch (1970) J. Mol. Biol. 48:443, by the search for similarity method of Pearson and Lipman (1988) Proc. Nat'l Acad. Sci. USA 85:2444, by computerized implementations of these algorithms (GAP, BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group, 575 Science Dr., Madison, WI), or by visual inspection (see generally Ausubel et al., supra).

One example of a useful algorithm is PILEUP. PILEUP creates a multiple sequence alignment from a group of related sequences using progressive, pairwise alignments to show relationship and percent sequence identity. It also plots a tree or dendogram showing the clustering relationships used to create the alignment. PILEUP uses a simplification of the progressive alignment method of Feng and Doolittle (1987) <u>J. Mol. Evol.</u> 35:351-360. method used is similar to the method described by Higgins and Sharp (1989) CABIOS 5:151-153. The program can align up to 300 sequences, each of a maximum length of 5,000 nucleotides or amino acids. The multiple alignment procedure begins with the pairwise alignment of the two most similar sequences, producing a cluster of two aligned sequences. This cluster is then aligned to the next most related sequence or cluster of aligned sequences. Two clusters of sequences are aligned by a simple extension of the pairwise alignment of two individual sequences. The final alignment is achieved by a series of progressive, pairwise alignments. The program is run by designating specific sequences and their amino acid or nucleotide coordinates for regions of sequence comparison and by designating the program parameters. For example, a reference sequence can be compared to other test sequences to determine the percent sequence identity relationship using the following parameters: default gap weight (3.00), default gap length weight (0.10), and weighted end gaps.

10 Another example of algorithm that is suitable for determining percent sequence identity and sequence similarity is the BLAST algorithm, which is described Altschul, et al. (1990) J. Mol. Biol. 215:403-410. Software for performing BLAST analyses is publicly 15 available through the National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov/). This algorithm involves first identifying high scoring sequence pairs (HSPs) by identifying short words of length W in the query sequence, which either match or satisfy some 20 positive-valued threshold score T when aligned with a word of the same length in a database sequence. referred to as the neighborhood word score threshold (Altschul, et al., supra). These initial neighborhood word hits act as seeds for initiating searches to find 25 longer HSPs containing them. The word hits are then extended in both directions along each sequence for as far as the cumulative alignment score can be increased. Extension of the word hits in each direction are halted when: the cumulative alignment score falls off by the 30 quantity X from its maximum achieved value; the cumulative score goes to zero or below, due to the accumulation of one or more negative-scoring residue alignments; or the end of either sequence is reached. The BLAST algorithm parameters W, T, and X determine the 35 sensitivity and speed of the alignment. The BLAST program uses as defaults a word length (W) of 11, the BLOSUM62 scoring matrix (see Henikoff and Henikoff (1989) Proc. Nat'l Acad. Sci. USA 89:10915) alignments (B) of 50, expectation (E) of 10, M=5, N=4, and a comparison of 40 both strands.

WO 99/03993 19

15

20

25

30

35

40

PCT/US98/14544

In addition to calculating percent sequence identity, the BLAST algorithm also performs a statistical analysis of the similarity between two sequences (see, e.g., Karlin and Altschul (1993) Proc. Nat'l Acad. Sci.

5 USA 90:5873-5787). One measure of similarity provided by the BLAST algorithm is the smallest sum probability (P(N)), which provides an indication of the probability by which a match between two nucleotide or amino acid sequences would occur by chance. For example, a nucleic acid is considered similar to a reference sequence if the smallest sum probability in a comparison of the test nucleic acid to the reference nucleic acid is less than about 0.1, more preferably less than about 0.01, and most preferably less than about 0.001.

A further indication that two nucleic acid sequences of polypeptides are substantially identical is that the polypeptide encoded by the first nucleic acid is immunologically cross reactive with the polypeptide encoded by the second nucleic acid, as described below. Thus, a polypeptide is typically substantially identical to a second polypeptide, for example, where the two peptides differ only by conservative substitutions. Another indication that two nucleic acid sequences are substantially identical is that the two molecules hybridize to each other under stringent conditions, as described below.

"Stringent conditions", in referring to homology or substantial similarity in the hybridization context, will be stringent combined conditions of salt, temperature, organic solvents, and other parameters, typically those controlled in hybridization reactions. The combination of parameters is more important than the measure of any single parameter. See, e.g., Wetmur and Davidson (1968) J. Mol. Biol. 31:349-370.

A nucleic acid probe which binds to a target nucleic acid under stringent conditions is specific for said target nucleic acid. Hybridization under stringent conditions should give a background of at least 2-fold over background, preferably at least 3-5 or more. Such a probe is typically more than 11 nucleotides in length,

and is sufficiently identical or complementary to a target nucleic acid over the region specified by the sequence of the probe to bind the target under stringent hybridization conditions.

SOCS14, SOCS15 (WDS11), SOCS17, SOCS18, SOCS19, or WDS12 protein from other mammalian species can be cloned and isolated by cross-species hybridization of closely related species. See, e.g., below. Similarity may be relatively low between distantly related species, and thus hybridization of relatively closely related species is advisable. Alternatively, preparation of an antibody preparation which exhibits less species specificity may be useful in expression cloning approaches.

The phrase "specifically binds to an antibody" or 15 "specifically immunoreactive with", when referring to a protein or peptide, refers to a binding reaction which is determinative of the presence of the protein in the presence of a heterogeneous population of proteins and other biological components. Thus, under designated 20 immunoassay conditions, the specified antibodies bind to a particular protein and do not significantly bind other proteins present in the sample. Specific binding to an antibody under such conditions may require an antibody that is selected for its specificity for a particular 25 protein. For example, antibodies raised to the protein immunogen with the amino acid sequence depicted in SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16 can be selected to obtain antibodies specifically immunoreactive with SOCS or WDS proteins and not with other proteins. 30 antibodies recognize proteins highly similar to the homologous SOCS or WDS protein.

III. Nucleic Acids

Primate or rodent SOCS or WDS protein is each

exemplary of a larger class of structurally and
functionally related proteins. These soluble proteins
will serve to transmit signals between different cell
types. The preferred embodiments, as disclosed, will be
useful in standard procedures to isolate genes from
different individuals or other species, e.g., warm

blooded animals, such as birds and mammals. Cross
hybridization will allow isolation of related genes
encoding proteins from individuals, strains, or species.
A number of different approaches are available to
successfully isolate a suitable nucleic acid clone based
upon the information provided herein. Southern blot
hybridization studies can qualitatively determine the
presence of homologous genes in human, monkey, rat,
mouse, dog, cow, and rabbit genomes under specific
hybridization conditions.

Complementary sequences will also be used as probes or primers. Based upon identification of the likely amino terminus, other peptides should be particularly useful, e.g., coupled with anchored vector or poly-A complementary PCR techniques or with complementary DNA of other peptides.

15

20

25

30

40

Techniques for nucleic acid manipulation of genes encoding SOCS or WDS proteins, such as subcloning nucleic acid sequences encoding polypeptides into expression vectors, labeling probes, DNA hybridization, and the like are described generally in Sambrook, et al. (1989)

Molecular Cloning: A Laboratory Manual (2nd ed.) Vol. 1-3, Cold Spring Harbor Laboratory, Cold Spring Harbor Press, NY, which is incorporated herein by reference.
This manual is hereinafter referred to as "Sambrook, et al."

There are various methods of isolating DNA sequences encoding SOCS or WDS proteins. For example, DNA is isolated from a genomic or cDNA library using labeled oligonucleotide probes having sequences identical or complementary to the sequences disclosed herein. Full-length probes may be used, or oligonucleotide probes may be generated by comparison of the sequences disclosed. Such probes can be used directly in hybridization assays to isolate DNA encoding SOCS or WDS proteins, or probes can be designed for use in amplification techniques such as PCR, for the isolation of DNA encoding SOCS or WDS proteins.

To prepare a cDNA library, mRNA is isolated from cells which expresses a SOCS or WDS protein. cDNA is

WO 99/03993 22

20

25

30

35

40

PCT/US98/14544

prepared from the mRNA and ligated into a recombinant vector. The vector is transfected into a recombinant host for propagation, screening, and cloning. Methods for making and screening cDNA libraries are well known. See Gubler and Hoffman (1983) <u>Gene</u> 25:263-269 and Sambrook, et al.

For a genomic library, the DNA can be extracted from tissue and either mechanically sheared or enzymatically digested to yield fragments of about 12-20 kb. The

10 fragments are then separated by gradient centrifugation and cloned in bacteriophage lambda vectors. These vectors and phage are packaged in vitro, as described in Sambrook, et al. Recombinant phage are analyzed by plaque hybridization as described in Benton and Davis

15 (1977) Science 196:180-182. Colony hybridization is carried out as generally described in e.g., Grunstein, et al. (1975) Proc. Natl. Acad. Sci. USA. 72:3961-3965.

DNA encoding a SOCS14 or SOCS15 protein can be identified in either cDNA or genomic libraries by its ability to hybridize with the nucleic acid probes described herein, e.g., in colony or plaque hybridization assays. The corresponding DNA regions are isolated by standard methods familiar to those of skill in the art. See, e.g., Sambrook, et al.

Various methods of amplifying target sequences, such as the polymerase chain reaction, can also be used to prepare DNA encoding SOCS or WDS proteins. Polymerase chain reaction (PCR) technology is used to amplify such nucleic acid sequences directly from mRNA, from cDNA, and from genomic libraries or cDNA libraries. The isolated sequences encoding SOCS or WDS proteins may also be used as templates for PCR amplification.

Typically, in PCR techniques, oligonucleotide primers complementary to two 5' regions in the DNA region to be amplified are synthesized. The polymerase chain reaction is then carried out using the two primers. See Innis, et al. (eds.) (1990) PCR Protocols: A Guide to Methods and Applications Academic Press, San Diego, CA. Primers can be selected to amplify the entire regions encoding a full-length SOCS or WDS protein or to amplify

40

smaller DNA segments as desired. Once such regions are PCR-amplified, they can be sequenced and oligonucleotide probes can be prepared from sequence obtained using standard techniques. These probes can then be used to isolate DNA's encoding SOCS or WDS proteins.

Oligonucleotides for use as probes are usually chemically synthesized according to the solid phase phosphoramidite triester method first described by Beaucage and Carruthers (1983) <u>Tetrahedron Lett.</u>

22(20):1859-1862, or using an automated synthesizer, as described in Needham-VanDevanter, et al. (1984) <u>Nucleic Acids Res.</u> 12:6159-6168. Purification of oligonucleotides is performed e.g., by native acrylamide gel electrophoresis or by anion-exchange HPLC as described in Pearson and Regnier (1983) <u>J. Chrom.</u>

described in Pearson and Regnier (1983) <u>J. Chrom.</u>
255:137-149. The sequence of the synthetic oligonucleotide can be verified using, e.g., the chemical degradation method of Maxam, A.M. and Gilbert, W. in Grossman, L. and Moldave (eds.) (1980) <u>Methods in</u>

20 Enzymology 65:499-560 Academic Press, New York.

Isolated nucleic acids encoding SOCS or WDS proteins were identified. The nucleotide sequences and corresponding open reading frames are provided in SEQ ID NO: 1 through 16.

These SOCS or WDS proteins exhibit limited similarity to portions other intracellular proteins. In particular, β-sheet and α-helix residues can be determined using, e.g., RASMOL program, see Sayle and Milner-White (1995) TIBS 20:374-376; or Gronenberg, et al. (1991) Protein Engineering 4:263-269; and other structural features are defined in Lodi, et al. (1994) Science 263:1762-1767.

This invention provides isolated DNA or fragments to encode a SOCS or WDS protein. In addition, this invention provides isolated or recombinant DNA which encodes a protein or polypeptide which is capable of hybridizing under appropriate conditions, e.g., high stringency, with the DNA sequences described herein. Said biologically active protein or polypeptide can be an intact protein, or fragment, and have an amino acid

sequence as disclosed in SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16, particularly natural embodiments. Preferred embodiments will be full length natural sequences. Further, this invention contemplates the use of isolated or recombinant DNA, or fragments thereof, which encode proteins which are homologous to a SOCS or WDS protein or which were isolated using cDNA encoding a SOCS or WDS protein as a probe. The isolated DNA can have the respective regulatory sequences in the 5' and 3' flanks, e.g., promoters, enhancers, poly-A addition signals, and others. Also embraced are methods for making expression vectors with these sequences, or for making, e.g., expressing and purifying, protein products.

A DNA which codes for a SOCS or WDS protein will be 15 particularly useful to identify genes, mRNA, and cDNA species which code for related or similar proteins, as well as DNAs which code for homologous proteins from different species. There are likely homologs in other species, including primates, rodents, canines, felines, 20 and birds. Various SOCS or WDS proteins should be homologous and are encompassed herein. However, even proteins that have a more distant evolutionary relationship to the antigen can readily be isolated under appropriate conditions using these sequences if they are 25 sufficiently homologous. Primate SOCS or WDS proteins are of particular interest.

Recombinant clones derived from the genomic sequences, e.g., containing introns, will be useful for transgenic studies, including, e.g., transgenic cells and organisms, and for gene therapy. See, e.g., Goodnow (1992) "Transgenic Animals" in Roitt (ed.) Encyclopedia of Immunology, Academic Press, San Diego, pp. 1502-1504; Travis (1992) Science 256:1392-1394; Kuhn, et al. (1991) Science 254:707-710; Capecchi (1989) Science 244:1288; Robertson (1987) (ed.) Teratocarcinomas and Embryonic Stem Cells: A Practical Approach, IRL Press, Oxford; and Rosenberg (1992) J. Clinical Oncology 10:180-199.

IV. Antibodies

10

15

20

25

30

35

40

Antibodies can be raised to various SOCS14 or SOCS15 proteins, including individual, polymorphic, allelic, strain, or species variants, and fragments thereof, both in their naturally occurring (full-length) forms and in their recombinant forms. Additionally, antibodies can be raised to SOCS or WDS proteins in either their active forms or in their inactive forms. Anti-idiotypic antibodies may also be used.

A. Antibody Production

A number of immunogens may be used to produce antibodies specifically reactive with SOCS or WDS proteins. Recombinant protein is the preferred immunogen for the production of monoclonal or polyclonal antibodies. Naturally occurring protein may also be used either in pure or impure form. Synthetic peptides, made using the human SOCS14 or SOCS15 protein sequences described herein, may also used as an immunogen for the production of antibodies to SOCS14 or SOCS15 proteins. Recombinant protein can be expressed in eukaryotic or prokaryotic cells as described herein, and purified as described. Naturally folded or denatured material can be used, as appropriate, for producing antibodies. Either monoclonal or polyclonal antibodies may be generated for subsequent use in immunoassays to measure the protein.

Methods of producing polyclonal antibodies are known to those of skill in the art. Typically, an immunogen, preferably a purified protein, is mixed with an adjuvant and animals are immunized with the mixture. The animal's immune response to the immunogen preparation is monitored by taking test bleeds and determining the titer of reactivity to the SOCS or WDS protein of interest. When appropriately high titers of antibody to the immunogen are obtained, usually after repeated immunizations, blood is collected from the animal and antisera are prepared. Further fractionation of the antisera to enrich for antibodies reactive to the protein can be done if desired. See, e.g., Harlow and Lane; or Coligan.

Monoclonal antibodies may be obtained by various techniques familiar to those skilled in the art.

Typically, spleen cells from an animal immunized with a desired antigen are immortalized, commonly by fusion with a myeloma cell (see, Kohler and Milstein (1976) <u>Eur. J. Immunol.</u> 6:511-519, incorporated herein by reference).

5 Alternative methods of immortalization include transformation with Epstein Barr Virus, oncogenes, or retroviruses, or other methods known in the art.

Colonies arising from single immortalized cells are screened for production of antibodies of the desired specificity and affinity for the antigen, and yield of the monoclonal antibodies produced by such cells may be

specificity and affinity for the antigen, and yield of the monoclonal antibodies produced by such cells may be enhanced by various techniques, including injection into the peritoneal cavity of a vertebrate host.

Alternatively, one may isolate DNA sequences which encode

a monoclonal antibody or a binding fragment thereof by
screening a DNA library from human B cells according,
e.g., to the general protocol outlined by Huse, et al.

(1989) Science 246:1275-1281.

Antibodies, including binding fragments and single 20 chain versions, against predetermined fragments of SOCS or WDS protein can be raised by immunization of animals with conjugates of the fragments with carrier proteins as described above. Monoclonal antibodies are prepared from cells secreting the desired antibody. These antibodies 25 can be screened for binding to normal or defective SOCS or WDS proteins, or screened for agonistic or antagonistic activity, e.g., effect on cell cycle progression or transcription of specific genes. These monoclonal antibodies will usually bind with at least a 30 K_D of about 1 mM, more usually at least about 300 μ M, typically at least about 10 µM, more typically at least about 30 µM, preferably at least about 10 µM, and more preferably at least about 3 μM or better.

In some instances, it is desirable to prepare

35 monoclonal antibodies from various mammalian hosts, such
as mice, rodents, primates, humans, etc. Description of
techniques for preparing such monoclonal antibodies may
be found in, e.g., Stites, et al. (eds.) <u>Basic and</u>
<u>Clinical Immunology</u> (4th ed.) Lange Medical Publications,

40 Los Altos, CA, and references cited therein; Harlow and

WO 99/03993 PCT/US98/14544

Lane (1988) Antibodies: A Laboratory Manual CSH Press; Goding (1986) Monoclonal Antibodies: Principles and Practice (2d ed.) Academic Press, New York, NY; and particularly in Kohler and Milstein (1975) Nature 256:495-497, which discusses one method of generating 5 monoclonal antibodies. Summarized briefly, this method involves injecting an animal with an immunogen. animal is then sacrificed and cells taken from its spleen, which are then fused with myeloma cells. result is a hybrid cell or "hybridoma" that is capable of 10 reproducing in vitro. The population of hybridomas is then screened to isolate individual clones, each of which secrete a single antibody species to the immunogen. this manner, the individual antibody species obtained are the products of immortalized and cloned single B cells 15 from the immune animal generated in response to a specific site recognized on the immunogenic substance.

Other suitable techniques involve selection of libraries of antibodies in phage or similar vectors. See, e.g., Huse, et al. (1989) "Generation of a Large 20 Combinatorial Library of the Immunoglobulin Repertoire in Phage Lambda, " Science 246:1275-1281; and Ward, et al. (1989) Nature 341:544-546. The polypeptides and antibodies of the present invention may be used with or without modification, including chimeric or humanized 25` antibodies. Frequently, the polypeptides and antibodies will be labeled by joining, either covalently or noncovalently, a substance which provides for a detectable signal. A wide variety of labels and conjugation techniques are known and are reported extensively in both 30 the scientific and patent literature. Suitable labels include radionuclides, enzymes, substrates, cofactors, inhibitors, fluorescent moieties, chemiluminescent moieties, magnetic particles, and the like. Patents, teaching the use of such labels include U.S. Patent Nos. 35 3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437; 4,275,149; and 4,366,241. Also, recombinant immunoglobulins may be produced. See, Cabilly, U.S.

25

Patent No. 4,816,567; and Queen, et al. (1989) <u>Proc.</u>
<u>Nat'l Acad. Sci. USA</u> 86:10029-10033.

The antibodies of this invention are useful for affinity chromatography in isolating SOCS or WDS protein. Columns can be prepared where the antibodies are linked to a solid support, e.g., particles, such as agarose, SEPHADEX, or the like, where a cell lysate or supernatant may be passed through the column, the column washed, followed by increasing concentrations of a mild denaturant, whereby purified SOCS or WDS protein will be released.

The antibodies may also be used to screen expression libraries for particular expression products. Usually the antibodies used in such a procedure will be labeled with a moiety allowing easy detection of presence of antigen by antibody binding.

Antibodies to SOCS or WDS proteins may be used for the identification of cell populations expressing the proteins. By assaying, e.g., by histology or otherwise, probably a disruptive assay which kills that sample of cells, the expression products of cells expressing SOCS or WDS proteins it is possible to diagnose disease, e.g., cancerous conditions.

Antibodies raised against each SOCS or WDS protein will also be useful to raise anti-idiotypic antibodies. These will be useful in detecting or diagnosing various immunological conditions related to expression of the respective antigens.

30 B. Immunoassays

A particular protein can be measured by a variety of immunoassay methods. For a review of immunological and immunoassay procedures in general, see Stites and Terr (eds.) (1991) <u>Basic and Clinical Immunology</u> (7th ed.).

Moreover, the immunoassays of the present invention can be performed in many configurations, which are reviewed extensively in Maggio (ed.) (1980) Enzyme Immunoassay CRC Press, Boca Raton, Florida; Tijan (1985) "Practice and Theory of Enzyme Immunoassays," Laboratory Techniques in

15

20

25

30

35

29

Biochemistry and Molecular Biology, Elsevier Science Publishers B.V., Amsterdam; and Harlow and Lane Antibodies, A Laboratory Manual, supra, each of which is incorporated herein by reference. See also Chan (ed.) (1987) Immunoassay: A Practical Guide Academic Press, Orlando, FL; Price and Newman (eds.) (1991) Principles and Practice of Immunoassays Stockton Press, NY; and Ngo (ed.) (1988) Non-isotopic Immunoassays Plenum Press, NY.

Immunoassays for measurement of SOCS or WDS proteins can be performed by a variety of methods known to those skilled in the art. In brief, immunoassays to measure the protein can be either competitive or noncompetitive binding assays. In competitive binding assays, the sample to be analyzed competes with a labeled analyte for specific binding sites on a capture agent bound to a solid surface. Preferably the capture agent is an antibody specifically reactive with SOCS or WDS proteins produced as described above. The concentration of labeled analyte bound to the capture agent is inversely proportional to the amount of free analyte present in the sample.

In a competitive binding immunoassay, the SOCS or WDS protein present in the sample competes with labeled protein for binding to a specific binding agent, for example, an antibody specifically reactive with the SOCS or WDS protein. The binding agent may be bound to a solid surface to effect separation of bound labeled protein from the unbound labeled protein. Alternately, the competitive binding assay may be conducted in liquid phase and a variety of techniques known in the art may be used to separate the bound labeled protein from the unbound labeled protein. Following separation, the amount of bound labeled protein is determined. The amount of protein present in the sample is inversely proportional to the amount of labeled protein binding.

Alternatively, a homogeneous immunoassay may be performed in which a separation step is not needed. In these immunoassays, the label on the protein is altered by the binding of the protein to its specific binding

WO 99/03993

10

15

PCT/US98/14544

30

agent. This alteration in the labeled protein results in a decrease or increase in the signal emitted by label, so that measurement of the label at the end of the immunoassay allows for detection or quantitation of the protein.

Qualitative or quantitative analysis of SOCS or WDS proteins may also be determined by a variety of noncompetitive immunoassay methods. For example, a two-site, solid phase sandwich immunoassay may be used. In this type of assay, a binding agent for the protein, for example an antibody, is attached to a solid support. A second protein binding agent, which may also be an antibody, and which binds the protein at a different site, is labeled. After binding at both sites on the protein has occurred, the unbound labeled binding agent is removed and the amount of labeled binding agent bound to the solid phase is measured. The amount of labeled binding agent bound is directly proportional to the amount of protein in the sample.

Western blot analysis can be used to determine the presence of SOCS or WDS proteins in a sample.

Electrophoresis is carried out, for example, on a tissue sample suspected of containing the protein. Following electrophoresis to separate the proteins, and transfer of the proteins to a suitable solid support, e.g., a nitrocellulose filter, the solid support is incubated with an antibody reactive with the protein. This antibody may be labeled, or alternatively may be detected by subsequent incubation with a second labeled antibody that binds the primary antibody.

The immunoassay formats described above employ labeled assay components. The label may be coupled directly or indirectly to the desired component of the assay according to methods well known in the art. A wide variety of labels and methods may be used. Traditionally, a radioactive label incorporating ³H, 125_I, 35_S, 14_C, or ³²P was used. Non-radioactive labels include proteins which bind to labeled antibodies, fluorophores, chemiluminescent agents, enzymes, and antibodies which can serve as specific binding pair

WO 99/03993 PCT/US98/14544

members for a labeled protein. The choice of label depends on sensitivity required, ease of conjugation with the compound, stability requirements, and available instrumentation. For a review of various labeling or signal producing systems which may be used, see U.S. Patent No. 4,391,904, which is incorporated herein by reference.

Antibodies reactive with a particular protein can also be measured by a variety of immunoassay methods. For a review of immunological and immunoassay procedures 10 applicable to the measurement of antibodies by immunoassay techniques, see Stites and Terr (eds.) Basic and Clinical Immunology (7th ed.) supra; Maggio (ed.) Enzyme Immunoassay, supra; and Harlow and Lane Antibodies, A Laboratory Manual, supra. 15

20

25

30

35

In brief, immunoassays to measure antisera reactive with SOCS or WDS proteins can be either competitive or noncompetitive binding assays. In competitive binding assays, the sample analyte competes with a labeled analyte for specific binding sites on a capture agent bound to a solid surface. Preferably the capture agent is a purified recombinant SOCS or WDS protein produced as described above. Other sources of these proteins, including isolated or partially purified naturally occurring protein, may also be used. Noncompetitive assays include sandwich assays, in which the sample analyte is bound between two analyte-specific binding reagents. One of the binding agents is used as a capture agent and is bound to a solid surface. The second binding agent is labeled and is used to measure or detect the resultant complex by visual or instrument means. number of combinations of capture agent and labeled binding agent can be used. A variety of different immunoassay formats, separation techniques, and labels can be also be used similar to those described above for the measurement of SOCS or WDS proteins.

Making SOCS or WDS proteins; Mimetics DNAs which encode a SOCS or WDS protein or fragments thereof can be obtained by chemical synthesis, screening 40

35

40

cDNA libraries, or by screening genomic libraries prepared from a wide variety of cell lines or tissue samples. Methods for doing so, or making expression vectors are described herein.

5 These DNAs can be expressed in a wide variety of host cells for the synthesis of a full-length protein or fragments which can in turn, e.g., be used to generate polyclonal or monoclonal antibodies; for binding studies; for construction and expression of modified molecules; 10 and for structure/function studies. Each SOCS or WDS protein or its fragments can be expressed in host cells that are transformed or transfected with appropriate expression vectors. By "transformed" is meant a cell into which (or into an ancestor of which) has been introduced, by means of recombinant techniques, a DNA 15 molecule that encodes a SOCS or WDS polypeptide. Heterologously expressed SOCS or WDS polypeptides can be substantially purified to be free of protein or cellular contaminants, other than those derived from the recombinant host, and therefore are particularly useful 20 in pharmaceutical compositions when combined with a pharmaceutically acceptable carrier and/or diluent. antigen, e.g., SOCS or WDS protein, or portions thereof, may be expressed as fusions with other proteins or 25 possessing an epitope tag.

Expression vectors are typically self-replicating DNA or RNA constructs containing the desired antigen gene or its fragments, usually operably linked to appropriate genetic control elements that are recognized in a suitable host cell. The specific type of control elements necessary to effect expression will depend upon the eventual host cell used. Generally, the genetic control elements can include a prokaryotic promoter system or a eukaryotic promoter expression control system, and typically include a transcriptional promoter, an optional operator to control the onset of transcription, transcription enhancers to elevate the level of mRNA expression, a sequence that encodes a suitable ribosome binding site, and sequences that terminate transcription and translation. All of the

WO 99/03993 PCT/US98/14544 33

10

15

20

25

30

35

40

associated elements both necessary and sufficient for the production of SOCS or WDS polypeptide will be in operable linkage with the nucleic acid encoding a SOCS or WDS polypeptide. Expression vectors also usually contain an origin of replication that allows the vector to replicate independently from the host cell.

The vectors of this invention contain DNAs which encode a SOCS or WDS protein, or a fragment thereof, typically encoding, e.g., a biologically active polypeptide, or protein. The DNA can be under the control of a viral promoter and can encode a selection This invention further contemplates use of such expression vectors which are capable of expressing eukaryotic cDNA coding for a SOCS or WDS protein in a prokaryotic or eukaryotic host, where the vector is compatible with the host and where the eukaryotic cDNA coding for the protein is inserted into the vector such that growth of the host containing the vector expresses the cDNA in question. Usually, expression vectors are designed for stable replication in their host cells or for amplification to greatly increase the total number of copies of the desirable gene per cell. It is not always necessary to require that an expression vector replicate in a host cell, e.g., it is possible to effect transient expression of the protein or its fragments in various hosts using vectors that do not contain a replication origin that is recognized by the host cell. It is also possible to use vectors that cause integration of a SOCS or WDS protein gene or its fragments into the host DNA by recombination, or to integrate a promoter which controls expression of an endogenous gene.

Vectors, as used herein, contemplate plasmids, viruses, bacteriophage, integratable DNA fragments, and other vehicles which enable the integration of DNA fragments into the genome of the host. Expression vectors are specialized vectors which contain genetic control elements that effect expression of operably linked genes. Plasmids are the most commonly used form of vector, but many other forms of vectors which serve an equivalent function are suitable for use herein. See,

15

20

25

30

35

e.g., Pouwels, et al. (1985 and Supplements) Cloning Vectors: A Laboratory Manual Elsevier, N.Y.; and Rodriquez, et al. (eds.) (1988) Vectors: A Survey of Molecular Cloning Vectors and Their Uses Buttersworth, Boston, MA.

Suitable host cells include prokaryotes, lower eukaryotes, and higher eukaryotes. Prokaryotes include both gram negative and gram positive organisms, e.g., E. coli and B. subtilis. Lower eukaryotes include yeasts, e.g., S. cerevisiae and Pichia, and species of the genus Dictyostelium. Higher eukaryotes include established tissue culture cell lines from animal cells, both of non-mammalian origin, e.g., insect cells, and birds, and of mammalian origin, e.g., human, primates, and rodents

of mammalian origin, e.g., human, primates, and rodents. Prokaryotic host-vector systems include a wide variety of vectors for many different species. As used herein, E. coli and its vectors will be used generically to include equivalent vectors used in other prokaryotes. A representative vector for amplifying DNA is pBR322 or its derivatives. Vectors that can be used to express these proteins or protein fragments include, but are not limited to, such vectors as those containing the lac promoter (pUC-series); trp promoter (pBR322-trp); Ipp promoter (the pIN-series); lambda-pP or pR promoters (pOTS); or hybrid promoters such as ptac (pDR540). See Brosius, et al. (1988) "Expression Vectors Employing Lambda-, trp-, lac-, and Ipp-derived Promoters", in Rodriguez and Denhardt (eds.) Vectors: A Survey of Molecular Cloning Vectors and Their Uses 10:205-236 Buttersworth, Boston, MA.

Lower eukaryotes, e.g., yeasts and Dictyostelium, may be transformed with SOCS or WDS protein sequence containing vectors. For purposes of this invention, the most common lower eukaryotic host is the baker's yeast, Saccharomyces cerevisiae. It will be used generically to represent lower eukaryotes although a number of other strains and species are also available. Yeast vectors typically consist of a replication origin (unless of the integrating type), a selection gene, a promoter, DNA

40

PCT/US98/14544 WO 99/03993

encoding the desired protein or its fragments, and sequences for translation termination, polyadenylation, and transcription termination. Suitable expression vectors for yeast include such constitutive promoters as 3-phosphoglycerate kinase and various other glycolytic enzyme gene promoters or such inducible promoters as the alcohol dehydrogenase 2 promoter or metallothionine promoter. Suitable vectors include derivatives of the following types: self-replicating low copy number (such as the YRp-series), self-replicating high copy number (such as the YEp-series); integrating types (such as the YIp-series), or mini-chromosomes (such as the YCpseries).

Higher eukaryotic tissue culture cells are typically the preferred host cells for expression of the 15 functionally active SOCS or WDS protein. In principle, many higher eukaryotic tissue culture cell lines may be used, e.g., insect baculovirus expression systems, whether from an invertebrate or vertebrate source. However, mammalian cells are preferred to achieve proper 20 processing, both cotranslationally and posttranslationally. Transformation or transfection and propagation of such cells is routine. Useful cell lines include HeLa cells, Chinese hamster ovary (CHO) cell lines, baby rat kidney (BRK) cell lines, insect cell 25 lines, bird cell lines, and monkey (COS) cell lines. Expression vectors for such cell lines usually include an origin of replication, a promoter, a translation initiation site, RNA splice sites (e.g., if genomic DNA is used), a polyadenylation site, and a transcription 30 termination site. These vectors also may contain a selection gene or amplification gene. Suitable expression vectors may be plasmids, viruses, or retroviruses carrying promoters derived, e.g., from such sources as from adenovirus, SV40, parvoviruses, vaccinia 35 virus, or cytomegalovirus. Representative examples of suitable expression vectors include pCDNA1; pCD, see Okayama, et al. (1985) Mol. Cell Biol. 5:1136-1142; pMC1neo Poly-A, see Thomas, et al. (1987) Cell 51:503-512; and a baculovirus vector such as pAC 373 or pAC 610. WO 99/03993

10

15

20

25

30

35

40

It is likely that SOCS or WDS proteins need not be glycosylated to elicit biological responses. However, it will occasionally be desirable to express a SOCS or WDS protein polypeptide in a system which provides a specific or defined glycosylation pattern. In this case, the usual pattern will be that provided naturally by the expression system. However, the pattern will be modifiable by exposing the polypeptide, e.g., in unglycosylated form, to appropriate glycosylating proteins introduced into a heterologous expression system. For example, the SOCS or WDS protein gene may be co-transformed with one or more genes encoding mammalian or other glycosylating enzymes. It is further understood that over glycosylation may be detrimental to SOCS or WDS protein biological activity, and that one of skill may perform routine testing to optimize the degree of glycosylation which confers optimal biological activity.

Furthermore, heterologously expressed proteins or polypeptides can also be expressed in plant cells. For plant cells viral expression vectors (e.g., cauliflower mosaic virus and tobacco mosaic virus) and plasmid expression vectors (e.g., T1 plasmid) are suitable. Such cells are available from a wide range of sources (e.g., the American Tissue Type Culture Collection, Rockland, MD; also, see for example, Ausubel, et al. (cur. ed. and Supplements; expression vehicles may be chosen from those provided e.g., in Pouwels, et al. (Cur. ed..) Cloning Vectors, A Laboratory Manual).

A SOCS or WDS protein, or a fragment thereof, may be engineered to be phosphatidyl inositol (PI) linked to a cell membrane, but can be removed from membranes by treatment with a phosphatidyl inositol cleaving enzyme, e.g., phosphatidyl inositol phospholipase-C. This releases the antigen in a biologically active form, and allows purification by standard procedures of protein chemistry. See, e.g., Low (1989) <u>Biochem. Biophys. Acta 988:427-454</u>; Tse, et al. (1985) <u>Science 230:1003-1008</u>; and Brunner, et al. (1991) <u>J. Cell Biol.</u> 114:1275-1283.

Now that SOCS or WDS proteins have been characterized, fragments or derivatives thereof can be

10

15

20

25

30

35

40

prepared by conventional processes for synthesizing These include processes such as are described peptides. in Stewart and Young (1984) Solid Phase Peptide Synthesis Pierce Chemical Co., Rockford, IL; Bodanszky and Bodanszky (1984) The Practice of Peptide Synthesis Springer-Verlag, New York, NY; and Bodanszky (1984) The Principles of Peptide Synthesis Springer-Verlag, New York, NY. For example, an azide process, an acid chloride process, an acid anhydride process, a mixed anhydride process, an active ester process (for example, p-nitrophenyl ester, N-hydroxysuccinimide ester, or cyanomethyl ester), a carbodiimidazole process, an oxidative-reductive process, or a dicyclohexylcarbodiimide (DCCD)/additive process can be used. Solid phase and solution phase syntheses are both applicable to the foregoing processes.

The prepared protein and fragments thereof can be isolated and purified from the reaction mixture by means of peptide separation, for example, by extraction, precipitation, electrophoresis and various forms of chromatography, and the like. The SOCS or WDS proteins of this invention can be obtained in varying degrees of purity depending upon its desired use. Purification can be accomplished by use of known protein purification techniques or by the use of the antibodies or binding partners herein described, e.g., in immunoabsorbant affinity chromatography. This immunoabsorbant affinity chromatography is carried out by first linking the antibodies to a solid support and then contacting the linked antibodies with solubilized lysates of appropriate source cells, lysates of other cells expressing the protein, or lysates or supernatants of cells producing the SOCS or WDS proteins as a result of recombinant DNA techniques, see below.

Multiple cell lines may be screened for one which expresses a SOCS or WDS protein at a high level compared with other cells. Various cell lines, e.g., a mouse thymic stromal cell line TA4, is screened and selected for its favorable handling properties. Natural SOCS or WDS proteins can be isolated from natural sources, or by

expression from a transformed cell using an appropriate expression vector. Purification of the expressed protein is achieved by standard procedures, or may be combined with engineered means for effective purification at high efficiency from cell lysates or supernatants. Epitope or other tags, e.g., FLAG or His6 segments, can be used for such purification features.

VI. Physical Variants

This invention also encompasses proteins or peptides having substantial amino acid sequence similarity with an amino acid sequence of a SOCS or WDS protein. Natural variants include individual, polymorphic, allelic, strain, or species variants.

Amino acid sequence similarity, or sequence identity, is determined by optimizing residue matches, if necessary, by introducing gaps as required. This changes when considering conservative substitutions as matches. Conservative substitutions typically include

- substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid; asparagine, glutamine; serine, threonine; lysine, arginine; and phenylalanine, tyrosine.

 Homologous amino acid sequences include natural
- polymorphic, allelic, and interspecies variations in each respective protein sequence. Typical homologous proteins or peptides will have from 50-100% similarity (if gaps can be introduced), to 75-100% similarity (if conservative substitutions are included) over fixed
- stretches of amino acids with the amino acid sequence of the SOCS or WDS protein. Similarity measures will be at least about 50%, generally at least 65%, usually at least 70%, preferably at least 75%, and more preferably at least 90%, and in particularly preferred embodiments, at
- least 96% or more. See also Needleham, et al. (1970) J.

 Mol. Biol. 48:443-453; Sankoff, et al. (1983) Time Warps,

 String Edits, and Macromolecules: The Theory and Practice
 of Sequence Comparison Chapter One, Addison-Wesley,

 Reading, MA; and software packages from IntelliGenetics,
- 40 Mountain View, CA; and the University of Wisconsin

.5

35

Genetics Computer Group, Madison, WI. Stretches of amino acids will be at least about 10 amino acids, usually about 20 amino acids, usually 50 amino acids, preferably 75 amino acids, and in particularly preferred embodiments at least about 100 amino acids. Identity can also be measures over amino acid stretches of about 98, 99, 110, 120, 130, etc.

Nucleic acids encoding mammalian SOCS or WDS proteins will typically hybridize to the nucleic acid sequence of SEQ ID NO: 1, 3, 5, 7, 9, 11, 13, or 15 under 10 stringent conditions. For example, nucleic acids encoding human SOCS or WDS proteins will normally hybridize to the nucleic acid of SEQ ID NO: 1, 3, 5, 7, 9, 11, 13, or 15 under stringent hybridization conditions. Generally, stringent conditions are selected 15 to be about 10° C lower than the thermal melting point (Tm) for the probe sequence at a defined ionic strength and pH. The Tm is the temperature (under defined ionic strength and pH) at which 50% of the target sequence 20 hybridizes to a perfectly matched probe. Typically, stringent conditions will be those in which the salt concentration is about 0.2 molar at pH 7 and the temperature is at least about 50° C. Other factors may significantly affect the stringency of hybridization, including, among others, base composition and size of the 25 complementary strands, the presence of organic solvents such as formamide, and the extent of base mismatching. A preferred embodiment will include nucleic acids which will bind to disclosed sequences in 50% formamide and 200 30 mM NaCl at 42° C.

Hybridizing nucleic acids to SOCS nucleic acid of the invention can be used as a cloning probe, a primer (e.g., a PCR primer), or a diagnostic probe. Hybridizing nucleic acids can be splice variants encoded by one of the SOCS genes described herein. Thus, the hybridizing nucleic acids may encode a polypeptide that is shorter or longer than the various forms of SOCS described herein. Hybridizing nucleic acids may also encode proteins that are related to SOCS (e.g., polypeptides encoded by genes

WO 99/03993 PCT/US98/14544

that include a portion having a relatively high degree of identity to a SOCS gene described herein).

40

An isolated SOCS or WDS protein encoding DNA can be readily modified by nucleotide substitutions, nucleotide deletions, nucleotide insertions, and short inversions of nucleotide stretches. These modifications result in novel DNA sequences which encode SOCS or WDS protein antigens, their derivatives, or proteins having highly similar physiological, immunogenic, or antigenic activity.

10

15

20

25

30

35

40

Modified sequences can be used to produce mutant antigens or to enhance expression. Enhanced expression may involve gene amplification, increased transcription, increased translation, and other mechanisms. Such mutant SOCS or WDS protein derivatives include predetermined or site-specific mutations of the respective protein or its fragments. "Mutant SOCS or WDS protein" encompasses a polypeptide otherwise falling within the homology definition of the human or rodent SOCS or WDS protein as set forth above, but having an amino acid sequence which differs from that of a SOCS or WDS protein as found in nature, whether by way of deletion, substitution, or insertion. In particular, "site specific mutant SOCS or WDS protein" generally includes proteins having significant similarity with a protein having a sequence of SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16, e.g., natural embodiments, and as sharing various biological activities, e.g., antigenic or immunogenic, with those sequences, and in preferred embodiments contain most or all of the disclosed sequence. This applies also to polymorphic variants from different individuals. Similar concepts apply to different SOCS or WDS proteins, particularly those found in various warm blooded animals, e.g., mammals and birds. As stated before, it is emphasized that descriptions are generally meant to encompass other SOCS or WDS proteins, not limited to the human embodiments specifically discussed.

The invention encompasses, but is not limited to, SOCS proteins and polypeptides that are functionally related to SOCS encoded by the specific sequence

WO 99/03993 PCT/US98/14544

identifiers of the present application. Functionally related proteins and polypeptides include any protein or polypeptide sharing a functional characteristic with SOCS of the present invention e.g., the ability to interact with Janus family tyrosine kinases or the ability to be induced by IL-2 receptor activation. Such functionally related SOCS polypeptides include, but are not limited to, additions or substitutions of amino acid residues within the amino acid sequence encoded by the SOCS sequences described herein which result in a silent change, thus producing a functionally equivalent SOCS polypeptide. Amino acid substitutions may be made on the basis of similarity in polarity, charge, solubility, hydrophobicity, hydrophilicity, and/or the amphiphatic nature of the residues involved.

10

15

20

25

30

35

40

For example, nonpolar (hydrophobic) amino acids include alanine, leucine, isoleucine, valine, proline, phenylalanine, tryptophan, and methionine; polar neutral amino acids include glycine, serine, threonine, cysteine, tyrosine, asparagine, and glutamine; positively charged (basic) amino acids include arginine, lysine, and histidine; and negatively charged (acidic) amino acids include aspartic acid and glutamic acid.

While random mutations can be made to SOCS nucleic acid (using well known random mutagenesis techniques) and the resulting SOCS polypeptides can be tested for activity, site-directed mutations of SOCS coding sequences can be engineered (using well known site-directed mutagenesis techniques) to generate mutant SOCS with increased function, e.g. greater inhibition of JANUS kinase activity or greater resistance to degradation.

To design functionally related and functionally variant SOCS polypeptides, it is useful to distinguish between conserved and variable amino residues using the homology comparison tables provided herein.

To preserve SOCS function, it is preferable that conserved residues remain unaltered and that the conformational folding of the SOCS functional sites be preserved. Preferably, alteration of non-conserved residues are carried out with conservative alterations

15

20

25

30

35

e.g., a basic amino acid is replaced by a different basic amino acid. To produce altered function variants, it is preferred to make non-conservative changes at variable and or conserved residues. Deletions at conserved and variable residues can also be used to create altered function variants.

Although site specific mutation sites are predetermined, mutants need not be site specific. or WDS protein mutagenesis can be conducted by making amino acid insertions or deletions. Substitutions. deletions, insertions, or any combinations may be generated to arrive at a final construct. Insertions include amino- or carboxyl- terminal fusions, e.g. epitope tags. Random mutagenesis can be conducted at a target codon and the expressed mutants can then be screened for the desired activity. Methods for making substitution mutations at predetermined sites in DNA having a known sequence are well known in the art, e.g., by M13 primer mutagenesis or polymerase chain reaction (PCR) techniques. See also, Sambrook, et al. (1989) and Ausubel, et al. (1987 and Supplements). The mutations in the DNA normally should not place coding sequences out of reading frames and preferably will not create complementary regions that could hybridize to produce secondary mRNA structure such as loops or hairpins.

The present invention also provides recombinant proteins, e.g., heterologous fusion proteins using segments from these proteins. A heterologous fusion protein is a fusion of proteins or segments which are naturally not normally fused in the same manner e.g., a marker polypeptide or fusion partner. For example, the polypeptide can be fused to a hexa-histidine tag to facilitate purification or bacterially expressed protein or a hemaglutinin tag to facilitate purification or protein expressed in eukaryotic cells. Thus, the fusion product of an immunoglobulin with a SOCS or WDS protein polypeptide is a continuous protein molecule having sequences fused in a typical peptide linkage, typically made as a single translation product and exhibiting

properties derived from each source peptide. A similar concept applies to heterologous nucleic acid sequences.

In addition, new constructs may be made from combining similar functional domains from other proteins.

5 For example, protein-binding or other segments may be "swapped" between different new fusion polypeptides or fragments. See, e.g., Cunningham, et al. (1989) Science 243:1330-1336; and O'Dowd, et al. (1988) J. Biol. Chem. 263:15985-15992. Thus, new chimeric polypeptides exhibiting new combinations of specificities will result from the functional linkage of protein-binding specificities and other functional domains.

VII. Functional Variants

40

The blocking of physiological response to SOCS or 15 WDS protein may result from the inhibition of binding of the protein to its binding partner, e.g., through competitive inhibition. Thus, in vitro assays of the present invention will often use isolated protein, membranes from cells expressing a recombinant membrane 20 associated SOCS or WDS protein, soluble fragments comprising binding segments of these proteins, or fragments attached to solid phase substrates. assays will also allow for the diagnostic determination of the effects of either binding segment mutations and 25 modifications, or protein mutations and modifications, e.g., protein analogs. This invention also contemplates the use of competitive drug screening assays, e.g., where neutralizing antibodies to antigen or binding partner fragments compete with a test compound for binding to the 30 In this manner, the antibodies can be used to detect the presence of a polypeptide which shares one or more antigenic binding sites of the protein and can also be used to occupy binding sites on the protein that might otherwise interact with a binding partner. 35

"Derivatives" of SOCS or WDS protein antigens include amino acid sequence mutants, glycosylation variants, and covalent or aggregate conjugates with other chemical moieties. Covalent derivatives can be prepared by linkage of functionalities to groups which are found

10

30

35

40

in SOCS or WDS protein amino acid side chains or at the N- or C- termini, by means which are well known in the art. These derivatives can include, without limitation, aliphatic esters or amides of the carboxyl terminus, or of residues containing carboxyl side chains, O-acyl derivatives of hydroxyl group-containing residues, and N-acyl derivatives of the amino terminal amino acid or amino-group containing residues, e.g., lysine or arginine. Acyl groups are selected from the group of alkyl-moieties including C3 to C18 normal alkyl, thereby forming alkanoyl aroyl species. Covalent attachment to carrier proteins may be important when immunogenic moieties are haptens.

In particular, glycosylation alterations are 15 included, e.g., made by modifying the glycosylation patterns of a polypeptide during its synthesis and processing, or in further processing steps. Particularly preferred means for accomplishing this are by exposing the polypeptide to glycosylating enzymes derived from 20 cells which normally provide such processing, e.g., mammalian glycosylation enzymes. Deglycosylation enzymes are also contemplated. Also embraced are versions of the same primary amino acid sequence which have other minor modifications, including phosphorylated amino acid 25 residues, e.g., phosphotyrosine, phosphoserine, or phosphothreonine, or other moieties, including ribosyl groups or cross-linking reagents.

A major group of derivatives are covalent conjugates of the SOCS or WDS protein or fragments thereof with other proteins or polypeptides. These derivatives can be synthesized in recombinant culture such as N- or C-terminal fusions or by the use of agents known in the art for their usefulness in cross-linking proteins through reactive side groups. Preferred protein derivatization sites with cross-linking agents are at free amino groups, carbohydrate moieties, and cysteine residues.

Fusion polypeptides between SOCS or WDS protein and other homologous or heterologous proteins are also provided. Heterologous polypeptides may be fusions between different surface markers, resulting in, e.g., a

hybrid protein exhibiting binding partner specificity. Likewise, heterologous fusions may be constructed which would exhibit a combination of properties or activities of the derivative proteins. Typical examples are fusions of a reporter polypeptide, e.g., luciferase, with a segment or domain of a protein, e.g., a segment involved in binding partner interaction, so that the presence or location of the fused protein may be easily determined. See, e.g., Dull, et al., U.S. Patent No. 4,859,609. Other gene fusion partners include bacterial β galactosidase, trpE, Protein A, ß-lactamase, alpha amylase, alcohol dehydrogenase, and yeast alpha mating factor. See, e.g., Godowski, et al. (1988) Science

241:812-816. The fusion partner can be constructed such that it can be cleaved off such that a protein of 15 substantially natural length is generated.

10

20

25

30

Such polypeptides may also have amino acid residues which have been chemically modified by phosphorylation, sulfonation, biotinylation, or the addition or removal of other moieties, particularly those which have molecular In some embodiments, shapes similar to phosphate groups. the modifications will be useful labeling reagents, or serve as purification targets, e.g., affinity proteins.

This invention also contemplates the use of derivatives of SOCS or WDS protein other than variations in amino acid sequence or glycosylation. derivatives may involve covalent or aggregative association with chemical moieties. These derivatives generally fall into the three classes: (1) salts, (2) side chain and terminal residue covalent modifications, and (3) adsorption complexes, for example with cell membranes. Such covalent or aggregative derivatives are useful as immunogens, as reagents in immunoassays, or in purification methods such as for affinity purification of proteinss or other binding proteins. For example, a SOCS 35 or WDS protein antigen can be immobilized by covalent bonding to a solid support such as cyanogen bromideactivated SEPHAROSE, by methods which are well known in the art, or adsorbed onto polyolefin surfaces, with or without glutaraldehyde cross-linking, for use in the 40

assay or purification of anti-SOCS or anti-WDS protein antibodies or its respective binding partner. The SOCS or WDS protein can also be labeled with a detectable group, e.g., radioiodinated by the chloramine T procedure, covalently bound to rare earth chelates, or conjugated to another fluorescent moiety for use in diagnostic assays. Purification of SOCS or WDS proteins may be effected by immobilized antibodies or binding partner.

10 Isolated SOCS or WDS protein genes will allow transformation of cells lacking expression of corresponding SOCS or WDS protein, e.g., either species types or cells which lack corresponding proteins and exhibit negative background activity. Expression of transformed genes will allow isolation of antigenically pure cell lines, with defined or single specie variants. This approach will allow for more sensitive detection and discrimination of the physiological effects of SOCS or WDS binding proteins. Subcellular fragments, e.g., cytoplasts or membrane fragments, can be isolated and used.

VIII. Binding Agent: SOCS or : WDS Protein Complexes A SOCS or WDS protein that specifically binds to or 25 that is specifically immunoreactive with an antibody generated against a defined immunogen, such as an immunogen consisting of the amino acid sequence of SEO ID NO: 2, 4, 6, 8, 10, 12, 14, or 16 is typically determined in an immunoassay. The immunoassay uses a polyclonal 30 antiserum which was raised to a protein of SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, or 16. This antiserum is selected to have low crossreactivity against other intracellular regulatory proteins and any such crossreactivity is removed by immunoabsorbtion prior to use in the 35 immunoassay.

In order to produce antisera for use in an immunoassay, the protein of desired sequence, e.g., SEQ ID NO: 2, 4, 6, 8, 10, 12, 14, and/or 16, is isolated as described herein. For example, recombinant protein may be produced in a mammalian cell line. An inbred strain

PCT/US98/14544

WO 99/03993

5

10

15

20

25

30

35

40

47

of mice such as Balb/c is immunized with the protein of appropriate sequence using a standard adjuvant, such as Freund's adjuvant, and a standard mouse immunization protocol (see Harlow and Lane, supra). Alternatively, a synthetic peptide, preferably near full length, derived from the sequences disclosed herein and conjugated to a carrier protein can be used an immunogen. Polyclonal sera are collected and titered against the immunogen protein in an immunoassay, for example, a solid phase immunoassay with the immunogen immobilized on a solid support. Polyclonal antisera with a titer of 10^4 or greater are selected and tested for their cross reactivity against other intracellular proteins, using a competitive binding immunoassay such as the one described in Harlow and Lane, supra, at pages 570-573. Preferably two intracellular proteins are used in this determination in conjunction with the desired SOCS or WDS protein.

Immunoassays in the competitive binding format can be used for the crossreactivity determinations. For example, a protein of SEQ ID NO: 2 or 4 can be immobilized to a solid support. Proteins added to the assay compete with the binding of the antisera to the immobilized antigen. The ability of the above proteins to compete with the binding of the antisera to the immobilized protein is compared to the protein of SEQ ID NO: 2 or 4. The percent crossreactivity for the above proteins is calculated, using standard calculations. Those antisera with less than 10% crossreactivity with each of the proteins listed above are selected and pooled. The cross-reacting antibodies are then removed from the pooled antisera by immunoabsorbtion with the above-listed proteins.

The immunoabsorbed and pooled antisera are then used in a competitive binding immunoassay as described above to compare a second protein to the immunogen protein (e.g., the SOCS14 or SOCS15 protein of SEQ ID NO: 2 and 6, or 4). In order to make this comparison, the two proteins are each assayed at a wide range of concentrations and the amount of each protein required to inhibit 50% of the binding of the antisera to the

15

20

25

30

35

immobilized protein is determined. If the amount of the second protein required is less than twice the amount of the protein, e.g., of SEQ ID NO: 2 that is required, then the second protein is said to specifically bind to an antibody generated to the immunogen.

It is understood that each of SOCS or WDS proteins are members of respective families of homologous proteins that comprise two or more genes. For a particular gene product, such as the human SOCS14 or SOCS15 protein, the term refers not only to the amino acid sequences disclosed herein, but also to other proteins that are polymorphic, allelic, non-allelic, or species variants. It is also understood that the term "SOCS14 or SOCS15 protein" includes nonnatural mutations introduced by deliberate mutation using conventional recombinant technology such as single site mutation, or by excising short sections of DNA encoding SOCS14 or SOCS15 proteins, or by substituting new amino acids, or adding new amino acids. Such minor alterations should substantially maintain the immunoidentity of the original molecule and/or its biological activity. Thus, these alterations include proteins that are specifically immunoreactive with a designated naturally occurring SOCS or WDS protein, for example, the human SOCS14 or SOCS15 protein shown in SEQ ID NO: 2 and 6, or 4 and 8. The biological properties of the altered proteins can be determined by expressing the protein in an appropriate cell line and measuring, e.g., a proliferative effect. Particular protein modifications considered minor would include conservative substitution of amino acids with similar chemical properties, as described above for the SOCS14 or SOCS15 protein as a whole. By aligning a protein optimally with the protein of SEQ ID NO: 2, 4, 6, or 8, and by using the conventional immunoassays described herein to determine immunoidentity, or by using proliferative assays, one can determine the protein compositions of the invention.

WO 99/03993 49

IX. Uses

10

15

20

The present invention provides reagents which will find use in diagnostic applications as described elsewhere herein, e.g., in the general description for developmental abnormalities, or below in the description of kits for diagnosis. Moreover, the SOCS proteins can block signaling via cytokine receptors.

SOCS or WDS nucleotides, e.g., human SOCS14 or SOCS15 DNA or RNA, may be used as a component in a forensic assay. For instance, the nucleotide sequences provided may be labeled using, e.g., ³²P or biotin and used to probe standard restriction fragment polymorphism blots, providing a measurable character to aid in distinguishing between individuals. Such probes may be used in well-known forensic techniques such as genetic fingerprinting. In addition, nucleotide probes made from SOCS or WDS sequences may be used in in situ assays to detect chromosomal abnormalities. For instance, rearrangements in the human chromosome encoding a SOCS14 or SOCS15 gene may be detected via well-known in situ techniques, using SOCS14 or SOCS15 probes in conjunction with other known chromosome markers.

Antibodies and other binding agents directed towards SOCS or WDS proteins or nucleic acids may be used to purify the corresponding SOCS or WDS molecule. As 25 described in the Examples below, antibody purification of SOCS or WDS protein components is both possible and practicable. Antibodies and other binding agents may also be used in a diagnostic fashion to determine whether SOCS or WDS protein components are present in a tissue 30 sample or cell population using well-known techniques described herein. The ability to attach a binding agent to a SOCS or WDS protein provides a means to diagnose disorders associated with SOCS or WDS protein misregulation. Antibodies and other SOCS or WDS protein 35 binding agents may also be useful as histological markers. It is likely that specific SOCS or WDS protein expression is limited to specific tissue types. By directing a probe, such as an antibody or nucleic acid to a SOCS14 or SOCS15 protein it is possible to use the 40

probe to distinguish tissue and cell types in situ or in vitro.

This invention also provides reagents with significant therapeutic value. The SOCS or WDS protein (naturally occurring or recombinant), fragments thereof, and antibodies thereto, along with compounds identified as having binding affinity to a SOCS or WDS protein, are useful in the treatment of conditions associated with abnormal physiology or development, including abnormal 10 proliferation, e.g., cancerous conditions, or degenerative conditions. Abnormal proliferation, regeneration, degeneration, and atrophy may be modulated by appropriate therapeutic treatment using the compositions provided herein. For example, a disease or 15 disorder associated with abnormal expression or abnormal signaling by a SOCS or WDS protein is a target for an agonist or antagonist of the protein. The proteins likely play a role in regulation or development of neuronal or hematopoietic cells, e.g., lymphoid cells, 20 which affect immunological responses.

For example, SOCS or WDS proteins likely play a role in T cell activation deficiencies in which patients develop clinical manifestations of T cell immunodeficiency such as opportunistic infections, 25 recurrent viral or bacterial infections, diarrhea, autoimmune hemolytic anemia, lymphoid hepatitis and dermatitis, and Hodgkin lymphoma, at various stages of childhood. An excess of SOCS proteins might lead to SCID-like (severe combined immunodeficiencies) syndromes 30 while a deficit of SOCS or WDS proteins may lead to malignant growth, for example, adult T cell leukemia/lymphoma is a disease associated with uncontrolled T-cell proliferation and is correlated at the molecular level with the presence of the IL-2 35 receptor (Schechter, G.P.; "Chronic Lymphocytic Leukemia" in Clinical Immunology; Principles and Practice, Rich (ed.) Mosby, St. Louis (Curr. ed.)). A model for adult T cell leukemia suggests that the disease may result from constitutive activation of the IL-2 receptor and its subsequent constitutive signaling cascade. 40

PCT/US98/14544 WO 99/03993

Administration of exogenous SOCS to effected T cells may modulate this disease.

Other abnormal developmental conditions are known in cell types shown to possess SOCS or WDS protein mRNA by northern blot analysis. See Berkow (ed.) The Merck Manual of Diagnosis and Therapy, Merck & Co., Rahway, N.J.; Thorn et al. Harrison's Principles of Internal Medicine, McGraw-Hill, N.Y.; and Rich (ed.) Clinical Immunology: Principles and Practice, Mosby, St. Louis (Curr. ed.). Developmental or functional abnormalities, 10 e.g., of the neuronal or immune system, cause significant medical abnormalities and conditions which may be susceptible to prevention or treatment using compositions provided herein.

Recombinant SOCS or WDS protein or SOCS or WDS 15 antibodies can be purified and then administered to a patient. These reagents can be combined for therapeutic use with additional active or inert ingredients, e.g., in conventional pharmaceutically acceptable carriers or diluents, e.g., immunogenic adjuvants, along with 20 physiologically innocuous stabilizers and excipients. These combinations can be sterile filtered and placed into dosage forms as by lyophilization in dosage vials or storage in stabilized aqueous preparations. This invention also contemplates use of antibodies or binding 25 fragments thereof, including forms which are not complement binding.

Drug screening using antibodies or fragments thereof can identify compounds having binding affinity to SOCS or WDS protein, including isolation of associated components. Subsequent biological assays can then be utilized to determine if the compound has intrinsic stimulating activity and is therefore a blocker or antagonist in that it blocks the activity of the protein. Likewise, a compound having intrinsic stimulating activity can activate the binding partner and is thus an agonist in that it simulates the activity of a SOCS or WDS protein. This invention further contemplates the therapeutic use of antibodies to SOCS or WDS protein as

30

35

antagonists. This approach should be particularly useful with other SOCS or WDS protein species variants.

Another therapeutic approach included within the invention involves direct administration of reagents or 5 compositions by any conventional administration techniques (for example but not restricted to local injection, inhalation, or administered systemically), to the subject with an immune, allergic or trauma disorder. The reagents, formulations or compositions included within the bounds and metes of the invention may 10 also be targeted to specific cells by any of the methods described herein. The actual dosage of reagent, formulation or composition that modulates an immune, disorder depends on many factors, including the size and 15 health of an organism, however one of one of ordinary skill in the art can use the following teachings describing the methods and techniques for determining clinical dosages. Spilker (1984) Guide to Clinical Studies and Developing Protocols, Raven Press Books, 20 Ltd., New York, pp. 7-13, 54-60; Spilker (1991) Guide to Clinical Trials, Raven Press, Ltd., New York, pp. 93-101; Craig and Stitzel (eds. 1986) Modern Pharmacology, 2d ed., Little, Brown and Co., Boston, pp. 127-33; Speight (ed. 1987) Avery's Drug Treatment: Principles and 25 Practice of Clinical Pharmacology and Therapeutics, 3d ed., Williams and Wilkins, Baltimore, pp. 50-56;

Practice of Clinical Pharmacology and Therapeutics, 3d ed., Williams and Wilkins, Baltimore, pp. 50-56; Tallarida, et al. (1988) Principles in General Pharmacology, Springer-Verlag, New York, pp. 18-20) to determine the appropriate dosage to use; but, generally, in the range of about between 0.5 fg/ml and 500 µg/ml inclusive final concentration are administered per day to an adult in any pharmaceutically-acceptable carrier.

The quantities of reagents necessary for effective therapy will depend upon many different factors,

including means of administration, target site, physiological state of the patient, and other medicants administered. Thus, treatment dosages should be titrated to optimize safety and efficacy. Typically, dosages used in vitro may provide useful guidance in the amounts useful for in situ administration of these reagents.

PCT/US98/14544 WO 99/03993

53

Animal testing of effective doses for treatment of particular disorders will provide further predictive indication of human dosage. Various considerations are described, e.g., in Gilman, et al. (eds.) (1990) Goodman and Gilman's: The Pharmacological Bases of Therapeutics (8th ed.) Pergamon Press; and (1990) Remington's Pharmaceutical Sciences (17th ed.) Mack Publishing Co., Easton, PA. Methods for administration are discussed therein and below, e.g., for oral, intravenous, intraperitoneal, or intramuscular administration, 10 transdermal diffusion, and others. Pharmaceutically acceptable carriers will include water, saline, buffers, and other compounds described, e.g., in the Merck Index, Merck & Co., Rahway, NJ. Dosage ranges would ordinarily be expected to be in amounts lower than 1 mM 15 concentrations, typically less than about 10 μM concentrations, usually less than about 100 nM, preferably less than about 10 pM (picomolar), and most preferably less than about 1 fM (femtomolar), with an appropriate carrier. Slow release formulations, or a 20 slow release apparatus will often be utilized for continuous administration.

SOCS or WDS protein, fragments thereof, and antibodies to it or its fragments, antagonists, and agonists, may be administered directly to the host to be 25 treated or, depending on the size of the compounds, it may be desirable to conjugate them to carrier proteins such as ovalbumin or serum albumin prior to their administration. Therapeutic formulations may be administered in any conventional dosage formulation. 30 While it is possible for the active ingredient to be administered alone, it is preferable to present it as a pharmaceutical formulation. Formulations typically comprise at least one active ingredient, as defined above, together with one or more acceptable carriers 35 thereof. Each carrier should be both pharmaceutically and physiologically acceptable in the sense of being compatible with the other ingredients and not injurious to the patient. Formulations include those suitable for oral, rectal, nasal, or parenteral (including 40

20

25

30

35

40

subcutaneous, intramuscular, intravenous and intradermal) administration. The formulations may conveniently be presented in unit dosage form and may be prepared by any methods well known in the art of pharmacy. See, e.g.,

- Gilman, et al. (eds.) (1990) Goodman and Gilman's: The Pharmacological Bases of Therapeutics (8th ed.) Pergamon Press; and (1990) Remington's Pharmaceutical Sciences (17th ed.) Mack Publishing Co., Easton, PA; Avis, et al. (eds.) (1993) Pharmaceutical Dosage Forms: Parenteral
- 10 Medications Dekker, NY; Lieberman, et al. (eds.) (1990)

 Pharmaceutical Dosgae Forms: Tablets Dekker, NY; and
 Lieberman, et al. (eds.) (1990) Pharmaceutical Dosage

 Forms: Disperse Systems Dekker, NY. The therapy of this invention may be combined with or used in association

 15 with other therapeutic agents.

Both the naturally occurring and the recombinant forms of the SOCS or WDS proteins of this invention are particularly useful in kits and assay methods which are capable of screening compounds for binding activity to the proteins. Several methods of automating assays have been developed in recent years so as to permit screening of tens of thousands of compounds in a short period. See, e.g., Fodor, et al. (1991) Science 251:767-773, and other descriptions of chemical diversity libraries, which describe means for testing of binding affinity by a plurality of compounds. The development of suitable assays can be greatly facilitated by the availability of large amounts of purified, soluble SOCS or WDS protein as provided by this invention.

For example, antagonists can normally be found once the protein has been structurally defined. Testing of potential protein analogs is now possible upon the development of highly automated assay methods using a purified binding partner. In particular, new agonists and antagonists will be discovered by using screening techniques described herein. Of particular importance are compounds found to have a combined binding affinity for multiple SOCS or WDS protein binding components, e.g., compounds which can serve as antagonists for species variants of a SOCS or WDS protein.

WO 99/03993 PCT/US98/14544 55

This invention is particularly useful for screening compounds by using recombinant protein in a variety of drug screening techniques. The advantages of using a recombinant protein in screening for specific binding partners include: (a) improved renewable source of the SOCS or WDS protein from a specific source; (b) potentially greater number of binding partners per cell giving better signal to noise ratio in assays; and (c) species variant specificity (theoretically giving greater biological and disease specificity).

10

15

20

25

30

35

40

One method of drug screening utilizes eukaryotic or prokaryotic host cells which are stably transformed with recombinant DNA molecules expressing a SOCS or WDS protein binding counterpart. Cells may be isolated which express a binding counterpart in isolation from any others. Such cells, either in viable or fixed form, can be used for standard protein binding assays. See also, Parce, et al. (1989) Science 246:243-247; and Owicki, et al. (1990) Proc. Nat'l Acad. Sci. USA 87:4007-4011, which describe sensitive methods to detect cellular responses. Competitive assays are particularly useful, where the cells (source of SOCS14 or SOCS15 protein) are contacted and incubated with a labeled binding partner or antibody having known binding affinity to the protein, such as $125_{I-antibody}$, and a test sample whose binding affinity to the binding composition is being measured. The bound and free labeled binding compositions are then separated to assess the degree of protein binding. The amount of test compound bound is inversely proportional to the amount of labeled binding partner binding to the known source. Any one of numerous techniques can be used to separate bound from free protein to assess the degree of protein binding. This separation step could typically involve a procedure such as adhesion to filters followed by washing, adhesion to plastic followed by washing, or centrifugation of the cell membranes. Viable cells could also be used to screen for the effects of drugs on SOCS or WDS protein mediated functions, e.g., second messenger levels, i.e., cell proliferation; inositol phosphate pool changes, transcription using a luciferase-type assay; and

10

15

20

25

30

35

40

others. Some detection methods allow for elimination of a separation step, e.g., a proximity sensitive detection system.

Another method utilizes membranes from transformed eukaryotic or prokaryotic host cells as the source of a SOCS or WDS protein. These cells are stably transformed with DNA vectors directing the expression of a SOCS or WDS protein, e.g., an engineered membrane bound form. Essentially, the membranes would be prepared from the cells and used in a protein binding assay such as the competitive assay set forth above.

Still another approach is to use solubilized, unpurified or solubilized, purified SOCS or WDS protein from transformed eukaryotic or prokaryotic host cells. This allows for a "molecular" binding assay with the advantages of increased specificity, the ability to automate, and high drug test throughput.

Another technique for drug screening involves an approach which provides high throughput screening for compounds having suitable binding affinity to a SOCS or WDS protein antibody and is described in detail in Geysen, European Patent Application 84/03564, published on September 13, 1984. First, large numbers of different small peptide test compounds are synthesized on a solid substrate, e.g., plastic pins or some other appropriate surface, see Fodor, et al., supra. Then all the pins are reacted with solubilized, unpurified or solubilized, purified SOCS or WDS protein antibody, and washed. The next step involves detecting bound SOCS or WDS protein antibody.

Rational drug design may also be based upon structural studies of the molecular shapes of the SOCS or WDS protein and other effectors or analogs. See, e.g., Methods in Enzymology vols 202 and 203. Effectors may be other proteins which mediate other functions in response to protein binding, or other proteins which normally interact with the binding partner. One means for determining which sites interact with specific other proteins is a physical structure determination, e.g., x-ray crystallography or 2 dimensional NMR techniques.

WO 99/03993 57

These will provide guidance as to which amino acid residues form molecular contact regions. For a detailed description of protein structural determination, see,

PCT/US98/14544

e.g., Blundell and Johnson (1976) <u>Protein Crystallography</u>
5 Academic Press, NY.

A purified SOCS or WDS protein can be coated directly onto plates for use in the aforementioned drug screening techniques. However, non-neutralizing antibodies to these proteins can be used as capture antibodies to immobilize the respective protein on the solid phase.

X. Kits

10

This invention also contemplates use of SOCS or WDS

proteins, fragments thereof, peptides, and their fusion
products in a variety of diagnostic kits and methods for
detecting the presence of SOCS or WDS protein or a
binding partner. Typically the kit will have a
compartment containing either a defined SOCS or WDS

protein peptide or gene segment or a reagent which
recognizes one or the other, e.g., binding partner
fragments or antibodies.

A kit for determining the binding affinity of a test compound to a SOCS or WDS protein would typically comprise a test compound; a labeled compound, e.g., a 25 binding agent or antibody having known binding affinity for the SOCS or WDS protein; a source of SOCS or WDS protein (naturally occurring or recombinant); and a means for separating bound from free labeled compound, such as a solid phase for immobilizing the SOCS or WDS protein. 30 Once compounds are screened, those having suitable binding affinity to the SOCS or WDS protein can be evaluated in suitable biological assays, as are well known in the art, to determine whether they act as agonists or antagonists to the binding partner. The 35 availability of recombinant SOCS or WDS protein polypeptides also provide well defined standards for calibrating such assays.

A preferred kit for determining the concentration of, for example, a SOCS or WDS protein in a sample would

40

typically comprise a labeled compound, e.g., binding partner or antibody, having known binding affinity for the SOCS or WDS protein, a source of SOCS or WDS protein (naturally occurring or recombinant), and a means for separating the bound from free labeled compound, for example, a solid phase for immobilizing the SOCS or WDS protein. Compartments containing reagents, and instructions, will normally be provided.

Antibodies, including antigen binding fragments, 10 specific for the SOCS or WDS protein or fragments thereof are useful in diagnostic applications to detect the presence of elevated levels of SOCS or WDS protein and/or its fragments. Such diagnostic assays can employ lysates, live cells, fixed cells, immunofluorescence, cell cultures, body fluids, and further can involve the 15 detection of antigens related to the protein in serum, or the like. Diagnostic assays may be homogeneous (without a separation step between free reagent and antigen-SOCS or -WDS protein complex) or heterogeneous (with a 20 separation step). Various commercial assays exist, such as radioimmunoassay (RIA), enzyme-linked immunosorbentassay (ELISA), enzyme immunoassay (EIA), enzyme-multiplied immunoassay technique (EMIT), substrate-labeled fluorescent immunoassay (SLFIA), and 25 the like. For example, unlabeled antibodies can be employed by using a second antibody which is labeled and which recognizes the antibody to a SOCS or WDS protein or to a particular fragment thereof. Similar assays have also been extensively discussed in the literature. See, 30 e.g., Harlow and Lane (1988) Antibodies: A Laboratory Manual, CSH Press, NY; Chan (ed.) (1987) Immunoassay: A Practical Guide Academic Press, Orlando, FL; Price and Newman (eds.) (1991) Principles and Practice of Immunoassay Stockton Press, NY; and Ngo (ed.) (1988) 35 Nonisotopic Immunoassay Plenum Press, NY.

Anti-idiotypic antibodies may have similar use to diagnose presence of antibodies against a SOCS or WDS protein, as such may be diagnostic of various abnormal states. For example, overproduction of SOCS or WDS protein may result in production of various immunological

WO 99/03993

59

5

10

15

25

40

or other medical reactions which may be diagnostic of abnormal physiological states, e.g., in cell growth, activation, or differentiation.

PCT/US98/14544

Frequently, the reagents for diagnostic assays are supplied in kits, so as to optimize the sensitivity of the assay. For the subject invention, depending upon the nature of the assay, the protocol, and the label, either labeled or unlabeled antibody or binding partner, or labeled SOCS or WDS protein is provided. This is usually in conjunction with other additives, such as buffers, stabilizers, materials necessary for signal production such as substrates for enzymes, and the like. Preferably, the kit will also contain instructions for proper use and disposal of the contents after use. Typically the kit has compartments for each useful reagent. Desirably, the reagents are provided as a dry lyophilized powder, where the reagents may be

reconstituted in an aqueous medium providing appropriate concentrations of reagents for performing the assay.

20 Many of the aforementioned constituents of the drug screening and the diagnostic assays may be used without modification, or may be modified in a variety of ways.

For example, labeling may be achieved by covalently or non-covalently joining a moiety which directly or indirectly provides a detectable signal. In any of these

assays, the protein, test compound, SOCS or WDS protein, or antibodies thereto can be labeled either directly or indirectly. Possibilities for direct labeling include label groups: radiolabels such as ¹²⁵I, enzymes (U.S.

Pat. No. 3,645,090) such as peroxidase and alkaline phosphatase, and fluorescent labels (U.S. Pat. No. 3,940,475) capable of monitoring the change in fluorescence intensity, wavelength shift, or fluorescence polarization. Possibilities for indirect labeling include biotinylation of one constituent followed by

include biotinylation of one constituent followed by binding to avidin coupled to one of the above label groups.

There are also numerous methods of separating the bound from the free protein, or alternatively the bound from the free test compound. The SOCS or WDS protein can

WO 99/03993

20

25

30

35

40

be immobilized on various matrices followed by washing. Suitable matrices include plastic such as an ELISA plate, filters, and beads. Methods of immobilizing the SOCS or WDS protein to a matrix include, without limitation, direct adhesion to plastic, use of a capture antibody, chemical coupling, and biotin-avidin. The last step in this approach involves the precipitation of protein/binding partner or antigen/antibody complex by any of several methods including those utilizing, e.g., 10 an organic solvent such as polyethylene glycol or a salt such as ammonium sulfate. Other suitable separation techniques include, without limitation, the fluorescein antibody magnetizable particle method described in Rattle, et al. (1984) Clin. Chem. 30:1457-1461, and the double antibody magnetic particle separation as described 15 in U.S. Pat. No. 4,659,678.

Methods for linking proteins or their fragments to the various labels have been extensively reported in the literature and do not require detailed discussion here. Many of the techniques involve the use of activated carboxyl groups either through the use of carbodismide or active esters to form peptide bonds, the formation of thioethers by reaction of a mercapto group with an activated halogen such as chloroacetyl, or an activated olefin such as maleimide, for linkage, or the like. Fusion proteins will also find use in these applications.

Another diagnostic aspect of this invention involves use of oligonucleotide or polynucleotide sequences taken from the sequence of a SOCS or WDS protein. These sequences can be used as probes for detecting levels of the SOCS or WDS protein message in samples from natural sources, or patients suspected of having an abnormal condition, e.g., cancer or developmental problem. The preparation of both RNA and DNA nucleotide sequences, the labeling of the sequences, and the preferred size of the sequences has received ample description and discussion in the literature. Normally an oligonucleotide probe should have at least about 14 nucleotides, usually at least about 18 nucleotides, and the polynucleotide probes may be up to several kilobases. Various labels may be

WO 99/03993 PCT/US98/14544 61

employed, most commonly radionuclides, particularly 32p. However, other techniques may also be employed, such as using biotin modified nucleotides for introduction into a polynucleotide. The biotin then serves as the site for binding to avidin or antibodies, which may be labeled with a wide variety of labels, such as radionuclides, fluorophores, enzymes, or the like. Alternatively, antibodies may be employed which can recognize specific duplexes, including DNA duplexes, RNA duplexes, DNA-RNA hybrid duplexes, or DNA-protein duplexes. The antibodies in turn may be labeled and the assay carried out where the duplex is bound to a surface, so that upon the formation of duplex on the surface, the presence of antibody bound to the duplex can be detected. The use of probes to the novel anti-sense RNA may be carried out using many conventional techniques such as nucleic acid hybridization, plus and minus screening, recombinational probing, hybrid released translation (HRT), and hybrid arrested translation (HART). This also includes amplification techniques such as polymerase chain reaction (PCR).

10

15

20

25

Diagnostic kits which also test for the qualitative or quantitative presence of other markers are also contemplated. Diagnosis or prognosis may depend on the combination of multiple indications used as markers. Thus, kits may test for combinations of markers. See, e.g., Viallet, et al. (1989) Progress in Growth Factor Res. 1:89-97.

The broad scope of this invention is best understood 30 with reference to the following examples, which are not intended to limit the invention to specific embodiments.

EXAMPLES

I. General Methods

- Many of the standard methods below are described or referenced, e.g., in Maniatis, et al. (Cur. ed..)

 Molecular Cloning, A Laboratory Manual Cold Spring Harbor Laboratory, Cold Spring Harbor Press, NY; Sambrook, et al. (1989) Molecular Cloning: A Laboratory Manual (2d ed.) Vols. 1-3, CSH Press, NY; Ausubel, et al., Biology Greene Publishing Associates, Brooklyn, NY; or Ausubel, et al. (1987 and Supplements) Current Protocols in Molecular Biology Wiley/Greene, NY; Innis, et al. (eds.) (1990) PCR Protocols: A Guide to Methods and Applications
- Academic Press, NY. Methods for protein purification include such methods as ammonium sulfate precipitation, column chromatography, electrophoresis, centrifugation, crystallization, and others. See, e.g., Ausubel, et al. (1987 and periodic supplements); Deutscher (1990) "Guide
- 20 to Protein Purification, "Methods in Enzymology vol. 182, and other volumes in this series; Coligan, et al. (1995 and supplements) Current Protocols in Protein Science
 John Wiley and Sons, New York, NY; P. Matsudaira (ed.) (1993) A Practical Guide to Protein and Peptide
- Purification for Microsequencing, Academic Press, San Diego, CA; and manufacturer's literature on use of protein purification products, e.g., Pharmacia, Piscataway, NJ, or Bio-Rad, Richmond, CA. Combination with recombinant techniques allow fusion to appropriate segments (epitope tags), e.g., to a FLAG segmence or an
 - segments (epitope tags), e.g., to a FLAG sequence or an equivalent which can be fused, e.g., via a protease-removable sequence. See, e.g., Hochuli (1989) Chemische Industrie 12:69-70; Hochuli (1990) "Purification of Recombinant Proteins with Metal Chelate Absorbent" in

 <u>Purification System QUIAGEN</u>, Inc., Chatsworth, CA.

Standard immunological techniques are described, 40 e.g., in Hertzenberg, et al. (eds. 1996) Weir's Hanbook

of Experimental Immunology vols 1-4, Blackwell Science;
Coligan (1991) Current Protocols in Immunology
Wiley/Greene, NY; and Methods in Enzymology volumes. 70,
73, 74, 84, 92, 93, 108, 116, 121, 132, 150, 162, and
5 163. Assays for neural cell biological activities are
described, e.g., in Wouterlood (ed. 1995) Neuroscience
Protocols modules 10, Elsevier; Methods in Neurosciences
Academic Press; and Neuromethods Humana Press, Totowa,
NJ. Methodology of developmental systems is described,
e.g., in Meisami (ed.) Handbook of Human Growth and
Developmental Biology CRC Press; and Chrispeels (ed.)
Molecular Techniques and Approaches in Developmental
Biology Interscience.

FACS analyses are described in Melamed, et al.

(1990) Flow Cytometry and Sorting Wiley-Liss, Inc., New York, NY; Shapiro (1988) Practical Flow Cytometry Liss, New York, NY; and Robinson, et al. (1993) Handbook of Flow Cytometry Methods Wiley-Liss, New York, NY.

- 20 II. Isolation of full length SOCS or WDS clones
 Standard methods are used to isolate full length
 genes. A cDNA library from an appropriate, e.g., human,
 cell, preferably a STAT containing cell type. The
 appropriate sequence is selected, and hybridization at
 25 high stringency conditions is performed to find a full
 length corresponding gene. It is noted that the mouse
 and human protein sequences are virtually identical.
- The full length, or appropriate fragments, of human genes are used to isolate a corresponding monkey or other primate gene. Preferably a full length coding sequence is used for hybridization. Similar source materials as indicated above are used to isolate natural genes, including genetic, polymorphic, allelic, or strain variants. Other species variants are also isolated using similar methods.

20

35

40

- IV. Isolation of an avian SOCS14 or SOCS15 clone
 An appropriate avian source is selected as above.

 Similar methods are utilized to isolate a species
 variant, though the level of similarity will typically be
 lower for avian protein as compared to a human to mouse
 sequence.
- V. Expression; purification; characterization
 Proteins of interest are immunoprecipitated and
 affinity purified as described above, e.g., from a
 natural or recombinant source.

Alternatively, with an appropriate clone from above, the coding sequence is inserted into an appropriate expression vector. This may be in a vector specifically selected for a prokaryote, yeast, insect, or higher vertebrate, e.g., mammalian expression system. Standard methods are applied to produce the gene product, preferably as a soluble secreted molecule, but will, in certain instances, also be made as an intracellular protein. Intracellular proteins typically require cell lysis to recover the protein, and insoluble inclusion bodies are a common starting material for further purificiation.

With a clone encoding a vertebrate SOCS14 or SOCS15

protein, recombinant production means are used, although
natural forms may be purified from appropriate sources.

The protein product is purified by standard methods of
protein purification, in certain cases, e.g., coupled
with immunoaffinity methods. Immunoaffinity methods are

used either as a purification step, as described above,
or as a detection assay to determine the separation
properties of the protein.

Preferably, the protein is secreted into the medium, and the soluble product is purified from the medium in a soluble form. Alternatively, as described above, inclusion bodies from prokaryotic expression systems are a useful source of material. Typically, the insoluble protein is solubilized from the inclusion bodies and refolded using standard methods. Purification methods are developed as described above.

15

25

30

35

The product of the purification method described above is characterized to determine many structural features. Standard physical methods are applied, e.g., amino acid analysis and protein sequencing. resulting protein is subjected to CD spectroscopy and other spectroscopic methods, e.g., NMR, ESR, mass spectroscopy, etc. The product is characterized to determine its molecular form and size, e.g., using gel chromatography and similar techniques. Understanding of the chromatographic properties will lead to more gentle or efficient purification methods.

Prediction of glycosylation sites may be made, e.g., as reported in Hansen, et al. (1995) Biochem. J. 308:801-813. However, as intracellular proteins, they are unlikely to be normally glycosylated.

The purified protein is also be used to identify other binding partners of SOCS or WDS as described, e.g., in Fields and Song (1989) Nature 340:245-246.

Preparation of antibodies against vertebrate SOCS or 20 VI. WDS

With protein produced, as above, animals are immunized to produce antibodies. Polyclonal antiserum is raised using non-purified antigen, though the resulting serum will exhibit higher background levels. Preferably, the antigen is purified using standard protein purification techniques, including, e.g., affinity chromatography using polyclonal serum indicated above. Presence of specific antibodies is detected using defined synthetic peptide fragments.

Polyclonal serum is raised against a purified antigen, purified as indicated above, or using, e.g., a plurality of, synthetic peptides. A series of overlapping synthetic peptides which encompass all of the full length sequence, if presented to an animal, will produce serum recognizing most linear epitopes on the protein. Such an antiserum is used to affinity purify protein, which is, in turn, used to introduce intact full length protein into another animal to produce another 40 antiserum preparation.

15

20

analyzed.

Similar techniques are used to generate induce monoclonal antibodies to either unpurified antigen, or, preferably, purified antigen.

5 VII. Cellular and tissue distribution

Distribution of the protein or gene products are determined, e.g., using immunohistochemistry with an antibody reagent, as produced above, by Western blotting of cell lysates, or by screening for nucleic acids encoding the respective protein. Either hybridization or PCR methods are used to detect DNA, cDNA, or message content. Histochemistry allows determination of the specific cell types within a tissue which express higher or lower levels of message or DNA. Antibody techniques are useful to quantitate protein in a biological sample, including a liquid or tissue sample. Immunoassays are developed to quantitate protein. Also FACS analysis may be used to evaluate expression in a cell population. Appropriate tissue samples or cell types are isolated and prepared for such detection. Commercial tissue blots are available, e.g., from Clontech (Mountain View, CA). Alternatively, cDNA library Southern blots can be

VIII. STAT interference by SOCS or WDS proteins
Standard methods for testing the biological activity
of the SOCS gene products in STAT signaling are
described, e.g., in Starr, et al. (1997) Nature 387:917921; Endo, et al. (1997) Nature 387:921-924; and Naka, et
al. Nature 387:924-929. Alternatively, JAK/STATs are
necessary for signal transduction. This assay is
performed as described, e.g., in Ho, et al. (1995) Mol.
Cell. Biol. 15:5043-5-53, and blockage with these gene
products may be tested.

In particular, the STAT5 dependent signaling in response to IL-2 is inhibited by the SOCS family member SOCS3.

30

IX. Antagonists of SOCS function

The inhibition of SOCS function may be effected by inhibitors of the specific interaction of these gene products and their respective STAT molecules. With the information on the specificity of pairings between these SOCS and respective STAT family members, compound libraries may be screened for blockage of such interactions. Thus, inhibitory action of the SOCS may be blocked with small molecule drug candidates.

10 Methods of using gene therapy are described, e.g., in Goodnow (1992) "Transgenic Animals" in Roitt (ed.)

Encyclopedia of Immunology, Academic Press, San Diego, pp. 1502-1504; Travis (1992) Science 256:1392-1394; Kuhn, et al. (1991) Science 254:707-710; Capecchi (1989)

15 Science 244:1288; Robertson (1987) (ed.) Teratocarcinomas and Embryonic Stem Cells: A Practical Approach, IRL Press, Oxford; and Rosenberg (1992) J. Clinical Oncology 10:180-199. Also included is the use of antisense RNA in gene therapy to block expression of the target gene, or proper splicing of gene transcripts.

X. Comparison of various SOCS embodiments

Tables 1 and 2 show comparison of various SOCS or WDS embodiments. Table 1 shows comparisons of the relevant portions of the gene products, particularly in the region of SOCS14 from Met168 to Leu293.

Table 2 shows alignment of the WDS "SOCSBOX protein" with a consensus of the mouse and human SOCS15 (WDS11) protein sequences, which are identical. See GenBank Accession numbers U88325; U88326; U88327; U88328; AB000676; AB000677; AB000710. This is aligned with the new WDS12, SEQ ID NO: 16.

All references cited herein are incorporated herein
by reference to the same extent as if each individual
publication or patent application was specifically and
individually indicated to be incorporated by reference in
its entirety for all purposes.

Many modifications and variations of this invention

can be made without departing from its spirit and scope,
as will be apparent to those skilled in the art. The
specific embodiments described herein are offered by way
of example only, and the invention is to be limited only
by the terms of the appended claims, along with the full
scope of equivalents to which such claims are entitled.

WHAT IS CLAIMED IS:

- 1. An isolated or recombinant polypeptide comprising:
- 5 a) at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 2 or 6;
 - at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 4 or 8;
 - c) at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 10;
 - d) at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 12;
 - e) at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 14; or
- 15 f) at least 17 contiguous amino acids from the coding portion of SEQ ID NO: 16.
- 2. The polypeptide of claim 1, comprising the amino acid sequence of:
 - a) a SOCS14 of SEQ ID NO: 2 or 6;
 - b) a SOCS15 (WDS11) of SEQ ID NO: 4 or 8;
 - c) a SOCS17 of SEQ ID NO: 10;
 - d) a SOCS18 of SEQ ID NO: 12;
- e) a SOCS19 of SEO ID NO: 14; or
 - f) a WDS12 of SEQ ID NO: 16.
- 3. A fusion protein comprising the polypeptide of claim 30 1 or 2.
 - 4. A binding compound which specifically binds to the polypeptide of claim 1 or 2.
- 35 5. The binding compound of claim 4 which is an antibody or antibody fragment.
 - 6. A nucleic acid encoding the polypeptide of claim 1 or 2.
- An expression vector comprising the nucleic acid of claim 6.
- A host cell comprising the vector of claim 7.
- 9. A process for recombinatly producing a polypeptide comprising culturing the host cell of claim 8 under conditions in which the polypeptide is expressed.

INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

(21) International Application Number: PCT/US98/14544 (22) International Filing Date: 17 July 1998 (17.07.98) (23) Priority Data: (30) Priority Data: (60/053,153	IU, ID, IL, IS, IP, KG, KR, D, MG, MK, MN, MX, NO, , SL, TJ, TM, TR, TT, UA,
(72) Inventor: JOHNSON, James, A.; 205 Mary Alice Drive, Los Gatos, CA 95032 (US). (74) Agents: MCLAUGHLIN, Jaye, P. et al.; Schering-Plough Corporation, Patent Dept., K-6-1 1990, 2000 Galloping Hill Road, Kenilworth, NJ 07033-0530 (US).	(AM, AZ, BY, KG, KZ, MD, (AT, BE, CH, CY, DE, DK, U, MC, NL, PT, SE), OAPI M, GA, GN, GW, ML, MR, limit for amending the claims of the receipt of amendments.

(57) Abstract

Purified genes encoding intracellular regulatory molecules from a human, reagents related thereto including purified proteins, specific antibodies, and nucleic acids encoding these molecules are provided. Methods of using said reagents and diagnostic kits are also provided.

International application No. PCT/US 98/14544

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)	
This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reaso	ns:
Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:	
Claims Nos.: because they relate to parts of the international Application that do not comply with the prescribed requirements to such an extent that no meaningful international Search can be carried out, specifically:	
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).	
Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)	
This International Searching Authority found multiple inventions in this international application, as follows:	
see additional sheet	
As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.	
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.	
3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:	
No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: Please see extra sheet, Subject 1.	
Remark on Protest The additional search fees were accompanied by the applicant's protest accompanied the payment of additional search fees.	st.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

1. Claims: (1-9) all partially

Human SOCS14. Production by genetic engineering. Antibody. Fusion protein.

2. Claims: (1-9) all partially

Murine SOCS15.Production by genetic engineering. Antibody. Fusion protein.

3. Claims: (1-9) all partially

Murine SOCS17. Production by genetic engineering. Antibody. Fusion protein.

4. Claims: (1-9) all partially

Human SOCS18. Production by genetic engineering. Antibody. Fusion protein.

5. Claims: (1-9) all partially

human ${\tt SOCS19}$. Production by genetic engineering. Antibody. Fusion protein.

6. Claims: (1-9) all partially

Murine WDS12. Production by genetic engineering. Antibody. Fusion protein.
